Unlocking the Power of Algebra: Real-World Examples and How to Solve Them

Algebra. The word itself can conjure up images of abstract equations and daunting numbers for many. But what if I told you that algebra isn't just confined to textbooks? It's a powerful tool that helps us understand and navigate the world around us every single day. From calculating discounts at your favorite store to planning a road trip, algebra is silently at work. This article is your friendly guide to understanding algebra word problems. We'll dive into various scenarios, break down how to approach them, and provide plenty of practical examples to build your confidence. Forget the fear; let's explore how algebra can be your secret weapon for problem-solving!

What Exactly is an Algebra Word Problem?

At its core, an algebra word problem is a scenario presented in words that requires you to use algebraic principles to find an unknown quantity. Instead of being given a straightforward equation like ' $x + 5 = 10$ ', you're presented with a story that hints at that relationship. The challenge lies in translating the words into mathematical expressions and equations. Think of it like being a detective. You're given clues (the words in the problem) and you need to use your reasoning skills (algebraic techniques) to uncover the truth (the unknown value).

Why Are Algebra Word Problems Important?

Beyond passing exams, mastering word problems is crucial for developing critical thinking and logical reasoning skills. They teach you to:

- **Identify key information:** Distinguish relevant details from those that are extraneous.
- **Model real-world situations:** Translate abstract concepts into concrete mathematical representations.
- **Develop problem-solving strategies:** Learn systematic approaches to tackle complex challenges.
- **Communicate mathematical ideas:** Articulate your reasoning and solutions clearly.

These skills are invaluable in virtually every career path and aspect of life.

Common Types of Algebra Word Problems with Examples

Let's get our hands dirty with some real-world examples. We'll explore different categories and see how algebra helps us find the answers.

1. Age Problems: Figuring Out the Years

Age problems are classic and often involve relationships between the ages of people at different points in time.

Example 1: Sarah is currently twice as old as her brother, Tom. In 5 years, Sarah will be 7 years older than Tom. How old are Sarah and Tom now?

Let's break it down:

- **Define variables:** Let 'S' represent Sarah's current age. Let 'T' represent Tom's current age.
- **Translate the first sentence into an equation:** "Sarah is currently twice as old as her brother, Tom." $S = 2T$
- **Translate the second sentence into an equation:** "In 5 years, Sarah will be 7 years older than Tom." Sarah's age in 5 years: $S + 5$ Tom's age in 5 years: $T + 5$ The equation: $S + 5 = (T + 5) + 7$
- **Now we have a system of two equations:** 1. $S = 2T$ 2. $S + 5 = T + 12$
- **Solve using substitution:** Since we know $S = 2T$ from the first equation, we can substitute '2T' for 'S' in the second equation. $(2T) + 5 = T + 12$ $2T + 5 = T + 12$ Subtract 'T' from both sides: $T + 5 = 12$ Subtract 5 from both sides: $T = 7$
- **Find Sarah's age:** Now that we know Tom is 7, we can use the first equation ($S = 2T$). $S = 2 \times 7$ $S = 14$

Answer: Sarah is currently 14 years old, and Tom is currently 7 years old.

Key takeaway for age problems: Carefully consider the "past," "present," and "future" ages and how they relate to each other.

2. Distance, Rate, and Time Problems: On the Move

These problems are ubiquitous in physics and everyday life. The fundamental formula is **Distance = Rate $\times$ Time** ($d = rt$).

Example 2: Two trains leave the same station at the same time, traveling in opposite directions. One train travels at a speed of 60 mph, and the other travels at a speed of 80 mph. How long will it take for the trains to be 420 miles apart?

Let's break it down:

- **Define variables:** Let 't' represent the time in hours (since the rates are in mph).
- **Distance for Train 1:** $d_1 = 60t$
- **Distance for Train 2:** $d_2 = 80t$
- **Understand the relationship:** Since they are traveling in opposite directions, the total distance between them is the sum of the distances each train has traveled. Total distance = $d_1 + d_2$
- **Set up the equation:** We know the total distance is 420 miles. $420 = 60t + 80t$ $420 = 140t$
- **Solve for 't':** $t = 420 / 140$ $t = 3$

Answer: It will take 3 hours for the trains to be 420 miles apart.

Related keywords: speed, velocity, travel time, journey, mph,

kilometers per hour. **Example 3:** A car leaves town A traveling towards town B at 50 mph. Two hours later, a second car leaves town A traveling towards town B at 70 mph. How long will it take the second car to catch up to the first car? **Let's break it down:** **Define variables:** Let 't' be the time (in hours) the second car travels. The first car travels for 't + 2' hours. **Distance for Car 1:** $d_1 = 50(t + 2)$ **Distance for Car 2:** $d_2 = 70t$ **Understand the relationship:** When the second car catches up, they will have traveled the same distance from town A. $d_1 = d_2$ **Set up the equation:** $50(t + 2) = 70t$ $50t + 100 = 70t$ $100 = 20t$ $t = 100 / 20$ $t = 5$ **Answer:** It will take the second car 5 hours to catch up to the first car. **Key takeaway for distance, rate, and time:** Always ensure your units are consistent (e.g., miles with mph, kilometers with km/h). Be mindful of whether objects are moving towards each other, away from each other, or one is trying to catch up to the other.

3. Mixture Problems: Blending Quantities

Mixture problems involve combining two or more substances with different concentrations or values to achieve a desired outcome. **Example 4:** A florist has 20 pounds of mixed nuts that sell for \$4 per pound. The florist wants to add walnuts that sell for \$6 per pound to create a new mixture that sells for \$5 per pound. How many pounds of walnuts should the florist add? **Let's break it down:** **Define variables:** Let 'w' represent the number of pounds of walnuts to be added. **Calculate the total cost of the initial mixture:** Cost of initial mixture = 20 pounds * \$4/pound = \$80 **Calculate the cost of the walnuts to be added:** Cost of walnuts = w pounds * \$6/pound = \$6w **Calculate the total weight of the new mixture:** Total weight = 20 + w pounds **Calculate the desired total cost of the new mixture:** Desired cost = (20 + w) pounds * \$5/pound = $5(20 + w) = 100 + 5w$ **Set up the equation:** The total cost of the initial mixture plus the cost of the added walnuts must equal the desired total cost of the new mixture. $\$80 + \$6w = \$100 + \$5w$ **Solve for 'w':** Subtract $5w$ from both sides: $\$80 + w = \100 Subtract $\$80$ from both sides: $w = 20$ **Answer:** The florist should add 20 pounds of walnuts. **Related keywords:** concentration, ratio, percentage, solution, combination. **Example 5:** A chemist has 10 liters of a 30% acid solution. How many liters of a 60% acid solution must be added to create a 50% acid solution? **Let's break it down:** **Define variables:** Let 'x' represent the number of liters of the 60% acid solution to be added. **Amount of acid in the initial solution:** $0.30 * 10 \text{ liters} = 3 \text{ liters of acid}$ **Amount of acid in the added solution:** $0.60 * x \text{ liters} = 0.6x \text{ liters of acid}$ **Total volume of the new solution:** $10 + x \text{ liters}$ **Desired amount of acid in the new solution (50% of the total volume):** $0.50 * (10 + x) \text{ liters} = 5 + 0.5x \text{ liters of acid}$ **Set up the equation:** The amount of acid from the initial solution plus the amount of acid from the added solution equals the total amount of acid in the new solution. $3 + 0.6x = 5 + 0.5x$ **Solve for 'x':** Subtract $0.5x$ from both sides: $3 + 0.1x = 5$ Subtract 3 from both sides: $0.1x = 2$ $x = 2 / 0.1$ $x = 20$ **Answer:** The chemist must add 20 liters of the 60% acid solution. **Key takeaway for mixture problems:** Focus on the quantity of the substance you are mixing (e.g., the amount of acid, the value of the nuts) and the total quantity.

4. Work Problems: Getting the Job Done

Work problems involve calculating the time it takes for individuals or groups to complete a task, either individually or together. The key is to think about the "rate of work." **Example 6:** If John can paint a fence in 4 hours, and Mary can paint the same fence in 6 hours, how long will it take them to paint the fence if they work together? **Let's break it down:** **Define variables:** Let 't' be the time (in hours) it takes them to paint the fence together. **John's rate of work:** In one hour, John paints $1/4$ of the fence. **Mary's rate of work:** In one hour, Mary paints $1/6$ of the fence. **Combined rate of work:** When working together, their rates add up. In one hour, they paint $(1/4 + 1/6)$ of the fence. **Find a common denominator for the rates:** The least common multiple of 4 and 6 is 12. $1/4 = 3/12$ $1/6 = 2/12$ **Combined rate =** $3/12 + 2/12 = 5/12$ of the fence per hour. **Set up the equation:** If they complete $5/12$ of the fence in one hour, then to complete the entire fence (which is 1 whole), it will take 't' hours such that: $(5/12) * t = 1$ **Solve for 't':** $t = 1 / (5/12)$ $t = 1 * (12/5)$ $t = 12/5 \text{ hours}$

Convert to hours and minutes: $12\frac{2}{5}$ hours = 2 and $\frac{2}{5}$ hours. $\frac{2}{5}$ of an hour = $(\frac{2}{5}) \times 60$ minutes = 24 minutes. **Answer:** It will take them 2.4 hours (or 2 hours and 24 minutes) to paint the fence together. **Related keywords:** efficiency, productivity, collaboration, tasks, completion time. **Example 7:** A machine can produce 100 widgets in 5 hours. A newer machine can produce 100 widgets in 4 hours. How long will it take to produce 100 widgets if both machines work together? **Let's break it down:** **Define variables:** Let 't' be the time (in hours) it takes them to produce 100 widgets together. **Rate of Machine 1:** Produces 100 widgets / 5 hours = 20 widgets/hour. **Rate of Machine 2:** Produces 100 widgets / 4 hours = 25 widgets/hour. **Combined rate of work:** 20 widgets/hour + 25 widgets/hour = 45 widgets/hour. **Set up the equation:** We want to produce 100 widgets. $45 \text{ widgets/hour} \times t \text{ hours} = 100 \text{ widgets}$ **Solve for 't':** $t = 100 / 45$ $t = 2\frac{2}{9}$ hours **Convert to a mixed number:** $2\frac{2}{9}$ hours = 2 and $\frac{2}{9}$ hours. **Answer:** It will take $2\frac{2}{9}$ hours (approximately 2.22 hours) for both machines to produce 100 widgets together. **Key takeaway for work problems:** Think about the "rate" at which work is done per unit of time. When working together, individual rates are added.

5. Geometry Word Problems: Shapes and Space

While not always purely algebraic, geometry word problems often involve setting up equations using geometric formulas and solving for unknown dimensions. **Example 8:** The length of a rectangle is 5 cm more than its width. If the perimeter of the rectangle is 34 cm, what are the dimensions of the rectangle? **Let's break it down:** **Define variables:** Let 'w' represent the width of the rectangle. Let 'l' represent the length of the rectangle. **Translate the first sentence into an equation:** "The length of a rectangle is 5 cm more than its width." $l = w + 5$ **Recall the formula for the perimeter of a rectangle:** $P = 2l + 2w$ **Substitute the given perimeter and the expression for 'l' into the perimeter formula:** $34 = 2(w + 5) + 2w$ **Solve for 'w':** $34 = 2w + 10 + 2w$ $34 = 4w + 10$ $24 = 4w$ $w = 6$ **Find the length 'l':** Use the equation $l = w + 5$. $l = 6 + 5$ $l = 11$ **Answer:** The dimensions of the rectangle are 11 cm (length) and 6 cm (width). **Related keywords:** area, volume, perimeter, circumference, dimensions, shape, measurement. **Key takeaway for geometry word problems:** Sketching a diagram can be incredibly helpful. Identify the relevant geometric formulas and substitute known values and expressions.

Algebra word problems serve as a vital bridge between abstract mathematical concepts and the practical challenges of everyday life, making them indispensable tools in both education and real-world problem solving. These problems transcend simple equations by embedding variables and relationships within realistic contexts, helping students and learners develop critical thinking, logical reasoning, and applied analytical skills. Unlike rote arithmetic questions, algebra word problems encourage a deeper engagement with mathematical structures, transforming symbols into stories that reflect tangible situations.

Understanding the Core Purpose of Algebra Word Problems

At their essence, algebra word problems translate real-world scenarios into mathematical expressions, where unknown quantities—often represented by variables—are tied to measurable relationships. For example, consider a problem involving the cost of apples: “A basket contains five more apples than twice the number of bananas. If each apple costs \$1.50 and each banana \$0.75, how much does the entire basket cost?” Here, variables like the number of bananas become the anchor points for constructing equations. This process not only reinforces algebraic manipulation but also teaches how to interpret and model real-life dynamics through mathematical language. The core insight lies in seeing algebra not merely as a set of rules, but as a dynamic tool for making sense of patterns and change.

Real-World Applications Across Disciplines

Algebra word problems find relevance across a broad spectrum of fields, underlining algebra's role as a universal language of problem solving. In business, problems often revolve around budgeting, profit margins, and inventory—such as determining how many units must be sold to break even, factoring in fixed and variable costs. In science, especially physics and chemistry, variables describe motion, reaction rates, or energy transformations, allowing students to translate experimental data into predictive formulas. Even in finance, problems involving interest rates, loan repayments, or investment growth rely on algebraic models to forecast outcomes. These applications demonstrate how algebra empowers individuals to navigate complexity with precision, offering a structured approach to decision-making in both personal and professional contexts.

Cognitive and Educational Benefits

Engaging with algebra word problems cultivates a multifaceted set of cognitive skills. Solving these problems requires careful reading and interpretation, as the wording often contains subtle cues that shape the underlying math. This sharpens comprehension and attention to detail. Beyond that, students practice breaking down multifaceted situations into manageable components—identifying knowns and unknowns, recognizing relationships, and formulating equations accordingly. This step-by-step reasoning builds logical rigor and enhances problem-solving resilience. Moreover, success in algebra word problems boosts confidence, reinforcing the belief that abstract math can yield concrete answers. Educators recognize these benefits as foundational to developing analytical thinking—a skill increasingly vital in an era defined by data and innovation.

Integrating Technology and Future Trends

As technology advances, the presentation and interaction with algebra word problems are evolving. Digital platforms now offer dynamic, interactive problem environments where variables can be manipulated in real time, and immediate feedback guides learners through trial and error. This shift supports personalized learning, allowing students to explore multiple solution paths at their own pace. Additionally, artificial intelligence is being leveraged

to generate adaptive problems tailored to individual learning levels, enhancing both engagement and effectiveness. Looking ahead, the integration of algebra word problems with real-time data—such as climate models, urban planning metrics, or health analytics—promises to deepen their relevance, preparing learners to tackle complex, interdisciplinary challenges with mathematical fluency. Algebra word problems are far more than academic exercises; they are gateways to understanding the quantitative fabric of the world. By grounding abstraction in reality, they nurture a mindset of inquiry, precision, and innovation—qualities essential for navigating the challenges of tomorrow.

Algebra word problems are the practical application of abstract mathematical concepts. They bridge the gap between theoretical equations and real-world scenarios, requiring students to translate words into mathematical expressions and solve for an unknown. Mastering these problems is crucial for building a strong foundation in mathematics and developing critical thinking skills. This article delves into various examples of algebra word problems, exploring their common types, effective problem-solving strategies, and the underlying algebraic principles they illustrate.

Unlocking the Power of Algebra Word Problems

At its core, algebra is about representing unknown quantities with variables and using equations to describe relationships between these quantities. Word problems are the perfect vehicle for this, transforming everyday situations into solvable mathematical puzzles. Whether you're calculating the cost of groceries, planning a trip, or understanding scientific phenomena, the ability to dissect and solve algebraic word problems is an invaluable life skill.

The term "algebra word problems" encompasses a vast array of scenarios. These problems often appear in textbooks, standardized tests like the SAT and GRE, and even in everyday decision-making. Understanding how to approach them systematically can demystify complex mathematical tasks and boost confidence in mathematical abilities. This exploration will highlight common patterns and provide practical examples to illustrate these concepts.

Common Types of Algebra Word Problems

Algebra word problems can be categorized based on the types of relationships they represent. Recognizing these categories helps in identifying the appropriate algebraic techniques to apply. Here are some of the most prevalent types:

1. Number Problems

These are often the introductory problems in algebra, focusing on relationships between unknown numbers. They typically involve phrases like "sum," "difference," "product," "quotient," "consecutive integers," or "a number is so much more than another."

Example: The sum of two numbers is 25. One number is 5 more than the other. Find the two numbers.

Analysis: Let the two numbers be represented by variables, say 'x' and 'y'. The problem translates into two equations:

1. $x + y = 25$ (The sum of two numbers is 25)
2. $x = y + 5$ (One number is 5 more than the other)

This system of linear equations can be solved using substitution or elimination. Substituting the second equation

into the first:

$$(y + 5) + y = 25$$

$$2y + 5 = 25$$

$$2y = 20$$

$$y = 10$$

Then, substitute $y = 10$ back into $x = y + 5$:

$$x = 10 + 5$$

$$x = 15$$

So, the two numbers are 10 and 15. This example showcases the power of defining variables and setting up simple linear equations.

2. Age Problems

Age problems involve comparing the ages of individuals at different points in time (past, present, or future). They often use phrases like "in x years," " x years ago," or "is twice as old as."

Example: Sarah is currently twice as old as her brother Tom. In 5 years, Sarah will be 8 years older than Tom. How old are Sarah and Tom now?

Analysis: Let Sarah's current age be ' S ' and Tom's current age be ' T '.

1. $S = 2T$ (Sarah is currently twice as old as Tom)

In 5 years:

1. Sarah's age will be $S + 5$
2. Tom's age will be $T + 5$

The second condition translates to:

1. $S + 5 = (T + 5) + 8$ (In 5 years, Sarah will be 8 years older than Tom)

Simplify the second equation:

$$S + 5 = T + 13$$

$$S = T + 8$$

Now we have a system of two equations:

1. $S = 2T$
2. $S = T + 8$

Equating the two expressions for S :

$$2T = T + 8$$

$$T = 8$$

Substitute $T = 8$ back into $S = 2T$:

$$S = 2 * 8$$

$$S = 16$$

Therefore, Sarah is 16 years old, and Tom is 8 years old. This problem highlights how to work with temporal changes in algebraic relationships.

3. Mixture Problems

Mixture problems involve combining two or more substances with different properties (like concentration or price) to achieve a desired final mixture. Key elements include the amount of each substance and its characteristic value.

Example: A chemist has 10 liters of a solution that is 20% acid. How many liters of a 50% acid solution must be added to create a solution that is 30% acid?

Analysis: Let 'x' be the number of liters of the 50% acid solution to be added. The total volume of the final solution will be $10 + x$ liters.

The amount of acid in the initial solution is $0.20 * 10 = 2$ liters.

The amount of acid in the added solution is $0.50 * x$ liters.

The amount of acid in the final solution will be $0.30 * (10 + x)$ liters.

The total amount of acid in the final solution is the sum of the acid from the initial solution and the added solution:

$$2 + 0.50x = 0.30(10 + x)$$

Now, solve for x:

$$2 + 0.50x = 3 + 0.30x$$

$$0.50x - 0.30x = 3 - 2$$

$$0.20x = 1$$

$$x = 1 / 0.20$$

$$x = 5$$

Therefore, 5 liters of the 50% acid solution must be added. Mixture problems often involve setting up equations based on the quantity and concentration (or value) of the components.

4. Distance, Rate, and Time Problems

These classic problems involve objects moving at certain speeds (rates) over specific periods (times) and covering certain distances. The fundamental formula is Distance = Rate $\times$ Time ($d = rt$).

Example: Two trains leave the same station at the same time, traveling in opposite directions. One train travels at 60 miles per hour, and the other travels at 70 miles per hour. How long will it take for them to be 390 miles apart?

Analysis: Let 't' be the time in hours they travel.

Distance traveled by the first train = $60t$ miles.

Distance traveled by the second train = $70t$ miles.

Since they are traveling in opposite directions, the total distance between them is the sum of the distances they each travel.

Total distance = Distance of train 1 + Distance of train 2

$$390 = 60t + 70t$$

$$390 = 130t$$

$$t = 390 / 130$$

$$t = 3$$

It will take 3 hours for the trains to be 390 miles apart. This type of problem tests the understanding of relative motion and the application of the $d=rt$ formula.

5. Work Problems

Work problems deal with the rate at which individuals or groups complete a task. The key concept is that the amount of work done is equal to the rate of work multiplied by the time spent working (Work = Rate $\times$ Time).

Example: If John can paint a house in 10 hours, and Mary can paint the same house in 15 hours, how long will it take them to paint the house if they work together?

Analysis: John's rate of work is $1/10$ of the house per hour.

Mary's rate of work is $1/15$ of the house per hour.

When they work together, their rates add up. Let 't' be the time it takes them to paint the house together.

Their combined rate is $(1/10) + (1/15)$ of the house per hour.

To add these fractions, find a common denominator, which is 30:

$$(3/30) + (2/30) = 5/30 = 1/6 \text{ of the house per hour.}$$

The work done together is their combined rate multiplied by the time 't':

$$(1/6) * t = 1 \text{ (representing one whole house painted)}$$

$$t = 6$$

It will take them 6 hours to paint the house together. Work problems often involve the concept of inverse proportion – the faster you work, the less time it takes.

Strategies for Tackling Algebra Word Problems

Success with algebra word problems hinges on a systematic approach. Here are some effective strategies:

1. Read and Understand

Carefully read the problem multiple times. Identify the unknown quantities and what is being asked. Underline key information and important phrases.

2. Define Variables

Assign a variable (like x, y, or a letter representing the item, e.g., 'c' for cost) to each unknown quantity. Clearly state what each variable represents.

3. Translate into Equations

Convert the words and relationships described in the problem into mathematical equations. Look for keywords that indicate operations (e.g., "sum" for +, "difference" for -, "product" for $\times$, "quotient" for $\div$).

4. Solve the Equations

Use appropriate algebraic techniques (substitution, elimination, factoring, quadratic formula, etc.) to solve the system of equations or the single equation you have formulated.

5. Check Your Answer

Substitute your solution back into the original word problem to ensure it makes sense in the context of the problem. Does the answer fit the conditions described? For example, if you're solving for age, a negative answer is not logical.

The Importance of Keywords and Phrasing

Certain keywords and phrases are crucial indicators of mathematical operations:

1. **Addition:** sum, total, increased by, more than, combined with, add
2. **Subtraction:** difference, less than, decreased by, subtracted from, minus, how much more
3. **Multiplication:** product, times, multiplied by, of (when referring to a fraction or percentage of a quantity), twice, three times
4. **Division:** quotient, divided by, per, ratio of
5. **Equality:** is, equals, is equal to, same as

Understanding these translations is fundamental to accurately setting up the algebraic expressions.

Advanced Applications and Real-World Relevance

While the examples above are foundational, algebra word problems extend into more complex domains. In physics, they are used to model motion, forces, and energy. In economics, they help in calculating profits, losses, and break-even points. In computer science, they can be used in algorithm design and optimization. The underlying principles of translating real-world scenarios into mathematical models remain consistent, regardless of complexity.

For instance, a problem involving linear regression in statistics could be phrased as finding the best-fit line for a set of data points, where the slope and y-intercept represent unknown coefficients. Similarly, optimization problems in calculus often start with a word problem that requires setting up a function to maximize or minimize.

Conclusion: Building Confidence Through Practice

Algebra word problems can initially seem daunting, but with consistent practice and a structured approach, they become more manageable and even enjoyable. By breaking down problems into smaller, logical steps, translating words into symbols, and diligently solving the resulting equations, students can develop a powerful problem-solving toolkit. The ability to articulate and solve mathematical problems is not just an academic pursuit; it's a vital skill that empowers individuals to navigate and understand the complexities of the modern world. Embracing these challenges is key to unlocking the full potential of algebraic reasoning.

Questions & Answers About examples of algebra word problems

No	Question	Answer
1	What's a classic word problem that helps illustrate basic algebraic concepts like variables and equations?	A common example is: 'Sarah has twice as many apples as John. If they have a total of 15 apples, how many apples does each person have?' Here, you can let 'x' represent the number of apples John has, and '2x' represent Sarah's apples. The equation becomes $x + 2x = 15$, leading to $3x = 15$, so $x = 5$. John has 5 apples, and Sarah has 10.
2	How can algebra help solve problems involving rates, like speed and distance?	Problems like 'A train travels 300 miles in 5 hours. What is its average speed?' use the formula distance = rate $\times$ time ($d = rt$). Rearranging, rate = distance / time. So, the speed is 300 miles / 5 hours = 60 mph.
3	Can you give an example of an algebra word problem involving percentages?	Sure! 'A store is having a 20% off sale. If a shirt originally cost \$50, what is the sale price?' You can find the discount amount by calculating 20% of \$50 ($0.20 \times \$50 = \10). Then, subtract the discount from the original price: $\$50 - \$10 = \$40$. The sale price is \$40.
4	What's a good word problem to practice setting up equations for ages?	Consider this: 'Maria is 5 years older than her brother, David. In 3 years, the sum of their ages will be 31. How old are they now?' Let 'd' be David's current age, so Maria's current age is 'd+5'. In 3 years, David will be 'd+3' and Maria will be 'd+5+3' (or 'd+8'). The equation is $(d+3) + (d+8) = 31$, which simplifies to $2d + 11 = 31$. Solving gives $2d = 20$, so $d = 10$. David is 10 and Maria is 15.
5	How do you approach word problems involving mixtures or solutions?	These often involve combining quantities with different concentrations. For example: 'How many liters of a 30% salt solution must be mixed with 20 liters of a 60% salt solution to obtain 100 liters of a 45% salt solution?' Let 'x' be the amount of the 30% solution. The equation would be $0.30x + 0.60(20) = 0.45(100)$. Solving this will give you the value of 'x'.
6	What are 'work' word problems and how does algebra solve them?	'Work' problems involve people or machines completing tasks. For instance: 'If Alice can paint a fence in 4 hours and Bob can paint it in 6 hours, how long will it take them to paint the fence together?' Their individual rates are $\frac{1}{4}$ fence per hour and $\frac{1}{6}$ fence per hour. Together, their rate is $\frac{1}{4} + \frac{1}{6} = \frac{5}{12}$ fence per hour. The time taken is the reciprocal of their combined rate: $\frac{12}{5}$ hours, or 2.4 hours.
7	Can you show an algebra word problem that uses inequalities?	Yes! 'A baker wants to make at least \$200 per day. Ingredients for each cake cost \$5, and they sell for \$15. If the baker must spend at least \$50 on other supplies, how many cakes must they sell?' Let 'c' be the number of cakes. The revenue is $15c$, and costs are $5c + 50$. The inequality is $15c - (5c + 50) \geq 200$, which simplifies to $10c - 50 \geq 200$. Solving gives $10c \geq 250$, so $c \geq 25$. They must sell at least 25 cakes.
8	What's a common scenario where quadratic equations appear in word problems?	Projectile motion or area problems often lead to quadratic equations. For example: 'A rectangular garden has a length that is 3 feet more than its width. If the area of the garden is 130 square feet, what are its dimensions?' Let 'w' be the width. The length is 'w+3'. The area is $w(w+3) = 130$. This expands to $w^2 + 3w - 130 = 0$, which can be factored or solved using the quadratic formula to find 'w'.

9	How can systems of equations be used to solve multi-variable word problems?	When a problem has multiple unknown quantities and multiple relationships between them, systems of equations are key. Example: 'A store sells two types of coffee beans: Brand A at \$10 per pound and Brand B at \$15 per pound. If a customer buys 5 pounds of coffee for \$60, how many pounds of each brand did they buy?' Let 'a' be pounds of Brand A and 'b' be pounds of Brand B. The equations are $a + b = 5$ and $10a + 15b = 60$. Solving this system gives the values for 'a' and 'b'.
