I. Fundamentals of Computer Graphics

This section lays the groundwork. Understanding these core

concepts is non-negotiable. Expect questions that test your foundational knowledge.

What is Computer Graphics?

Answer: Computer Graphics is a field of computer science that deals with generating and manipulating images, drawings, and other visual representations using computers. It involves the creation, storage, and manipulation of models and pictures that are used in computer systems.

Keywords: computer graphics definition, visual representation, image generation, digital art.

What are the applications of Computer Graphics?

Answer: The applications are vast and diverse. We see computer graphics everywhere, including:

1. **Entertainment:** Video games, animated films, special effects in movies.
2. **Design & Engineering:** CAD (Computer-Aided Design), architectural visualization, product design.
3. **Medical Imaging:** Visualization of CT scans, MRI scans, surgical planning.
4. **Data Visualization:** Charts, graphs, and infographics to represent complex data.

5. **User Interfaces:** Graphical User Interfaces (GUIs) for software and operating systems.
6. **Simulation:** Flight simulators, driving simulators, scientific simulations.

Keywords: computer graphics applications, CAD, animation, video games, medical visualization, data visualization.

Explain the Raster Scan and Random Scan display technologies.

Answer:

1. **Raster Scan:** In this approach, the screen is divided into a grid of pixels. The electron beam scans the screen line by line (from top to bottom, left to right) and illuminates the pixels to form the image. The image is stored in a frame buffer. This is the most common display technology today.
2. **Random Scan:** In this method, the electron beam moves directly to the points that need to be illuminated. It draws lines and shapes directly. It's more suited for line-drawing displays and can produce much sharper images but is generally more expensive and complex.

Keywords: raster scan, random scan, display technologies, frame buffer, pixels, electron beam.

What is a Pixel and a Resolution?

Answer:

1. **Pixel:** A pixel (picture element) is the smallest controllable element of a picture represented on a screen. It's a tiny dot that has a specific color and intensity.
2. **Resolution:** Resolution refers to the number of pixels that can be displayed along the width and height of a screen. A higher resolution means more pixels, resulting in a sharper and more detailed image (e.g., 1920x1080).

Keywords: pixel, resolution, screen resolution, image detail, pixel density.

What is a Frame Buffer?

Answer: A frame buffer is a portion of memory that stores the pixel information for a complete image. When a raster scan display is refreshed, it reads the pixel values from the frame buffer to display the image. It essentially acts as a map of the screen, telling each pixel what color to be.

Keywords: frame buffer, memory, pixel data, refresh rate, raster display.

What is a Graphics Card/GPU?

Answer: A Graphics Processing Unit (GPU), often referred to

as a graphics card, is a specialized electronic circuit designed to rapidly manipulate and alter memory to accelerate the creation of images intended for output to a display device. GPUs are highly parallel processors, making them ideal for tasks like rendering 3D graphics and video processing.

Keywords: GPU, graphics card, hardware acceleration, rendering, parallel processing.

Explain the difference between vector graphics and raster graphics.

Answer:

1. **Raster Graphics:** These are based on pixels. Images are composed of a grid of colored dots. They are resolution-dependent, meaning they lose quality when scaled up. Examples: JPG, PNG, GIF.
2. **Vector Graphics:** These are based on mathematical equations that define points, lines, curves, and shapes. They are resolution-independent, meaning they can be scaled infinitely without losing quality. Examples: SVG, AI, EPS.

Keywords: vector graphics, raster graphics, pixel-based, mathematical equations, scalability, image formats.

II. Geometric Transformations

Transformations are fundamental to manipulating objects in 2D and 3D space. You'll definitely be asked about these.

What are the basic 2D geometric transformations?

Answer: The basic 2D geometric transformations are:

1. **Translation:** Moving an object from one position to another without changing its orientation.
2. **Rotation:** Turning an object around a fixed point (the pivot point).
3. **Scaling:** Enlarging or shrinking an object uniformly or non-uniformly.

Keywords: 2D transformations, translation, rotation, scaling, geometric manipulation.

Explain 3D geometric transformations.

Answer: Similar to 2D, 3D transformations involve moving, rotating, and scaling objects, but in three dimensions (X, Y, and Z axes). Common 3D transformations include:

1. **3D Translation:** Shifting an object along the X, Y, and Z axes.
2. **3D Rotation:** Rotating an object around an axis (e.g., X-axis,

Y-axis, Z-axis, or an arbitrary axis).

3. **3D Scaling:** Adjusting the size of an object along the X, Y, and Z axes.
4. **Shearing:** Distorting the shape of an object by shifting its coordinates along one or more axes.

Keywords: 3D transformations, 3D translation, 3D rotation, 3D scaling, shearing, XYZ axis.

What is a transformation matrix? Why is it used?

Answer: A transformation matrix is a matrix used to represent a geometric transformation. By multiplying the coordinate of a point or object by the transformation matrix, we can obtain the new coordinates of the transformed object. Matrices are used because they provide a concise and efficient way to represent and combine multiple transformations.

Keywords: transformation matrix, matrix representation, geometric transformations, matrix multiplication, coordinate system.

Explain the concept of Homogeneous Coordinates and why they are used in graphics.

Answer: Homogeneous coordinates are a system where each

point in an N-dimensional space is represented by $N+1$ coordinates. In 2D graphics, we use (x, y, w) instead of (x, y) . For example, a 2D point (x, y) becomes $(x, y, 1)$ in homogeneous coordinates. They are crucial because they allow us to represent translation as a matrix multiplication, just like rotation and scaling. This enables us to combine all transformations into a single matrix, simplifying the process.

Keywords: homogeneous coordinates, 2D graphics, 3D graphics, matrix representation, translation, unified transformations.

What is composite transformation?

Answer: A composite transformation is a sequence of multiple transformations applied to an object. Instead of applying each transformation individually, we can combine them into a single composite transformation matrix. This is achieved by multiplying the individual transformation matrices in the correct order. This significantly speeds up rendering.

Keywords: composite transformation, combined transformations, transformation order, matrix concatenation, efficiency.

What is the difference between viewing

transformation and modeling transformation?

Answer:

1. **Modeling Transformation:** These transformations are applied to an object to define its position, orientation, and size in the world coordinate system. It's about how the object is built or modeled.
2. **Viewing Transformation:** These transformations define how the 3D world is viewed by the camera. It involves positioning and orienting the camera in the world and defining the projection (perspective or orthographic) that converts 3D coordinates to 2D screen coordinates.

Keywords: modeling transformation, viewing transformation, world coordinates, camera, projection, coordinate systems.

III. Graphics Primitives and Algorithms

This section focuses on how basic shapes and lines are drawn on the screen.

What are graphics primitives? Give examples.

Answer: Graphics primitives are the fundamental building blocks of computer graphics. They are the simplest graphical elements that a graphics system can draw. Common examples include:

1. Points
2. Lines
3. Polygons (triangles, quadrilaterals, etc.)
4. Circles and Ellipses
5. Text

Keywords: graphics primitives, fundamental elements, points, lines, polygons, shapes.

Explain Bresenham's Line Algorithm.

Answer: Bresenham's Line Algorithm is an efficient algorithm for drawing lines on a raster display. It uses only integer arithmetic, avoiding the need for floating-point calculations or division, which makes it very fast. The algorithm incrementally determines which pixel is closest to the true line path at each step, minimizing the error.

Keywords: Bresenham's line algorithm, line drawing algorithm, rasterization, integer arithmetic, efficiency.

Explain Bresenham's Circle Algorithm.

Answer: Similar to the line algorithm, Bresenham's Circle Algorithm is an efficient method for drawing circles using integer arithmetic. It generates the pixels of a circle by choosing the best pixel in each octant and then reflecting those pixels to generate the entire circle. It also focuses on minimizing error and computational cost.

Keywords: Bresenham's circle algorithm, circle drawing, rasterization, integer arithmetic, octants.

What is the midpoint circle drawing algorithm?

Answer: The midpoint circle drawing algorithm is another efficient algorithm for drawing circles. It determines which of two candidate pixels is closer to the ideal circle path by evaluating a decision parameter at the midpoint between them. Like Bresenham's, it uses integer arithmetic for speed.

Keywords: midpoint circle algorithm, circle drawing, rasterization, decision parameter, integer arithmetic.

What is Polygon Filling? Explain different methods.

Answer: Polygon filling is the process of coloring the interior of a polygon. Common methods include:

1. **Scan-Line Fill Algorithm:** This algorithm scans the screen line by line. For each scan line that intersects the polygon, it identifies the edge intersections and fills the pixels between the intersections.
2. **Seed-Fill Algorithm (Flood Fill):** This algorithm starts from a seed point inside the polygon and recursively colors adjacent pixels that have the same initial color until the

boundary of the polygon is reached.

Keywords: polygon filling, scan-line fill, flood fill, seed-fill algorithm, rasterization, interior coloring.

What is a scan-line?

Answer: In raster graphics, a scan-line is a single horizontal line of pixels across the display. Display devices, especially older CRT monitors, would draw images by scanning across these lines sequentially. Algorithms like the scan-line fill algorithm utilize this concept.

Keywords: scan-line, raster display, horizontal line, pixel row, scan-line algorithms.

IV. Clipping

Clipping is essential for displaying only the visible parts of objects within a defined window.

What is Clipping? Explain different types.

Answer: Clipping is the process of removing parts of an image or object that lie outside a specified boundary or window. The main types are:

1. **Point Clipping:** Determining if a point is inside or outside the clipping region.

2. **Line Clipping:** Determining which segments of a line are inside the clipping region.
3. **Polygon Clipping:** Determining which parts of a polygon lie inside the clipping region.
4. **Text Clipping:** Clipping text strings that extend beyond the clipping boundary.

Keywords: clipping, line clipping, polygon clipping, clipping window, visibility, boundary.

Explain the Cohen-Sutherland Line Clipping Algorithm.

Answer: The Cohen-Sutherland algorithm is a widely used line clipping algorithm. It divides the 2D space into nine regions using four "outcodes." By analyzing the outcodes of the endpoints of a line segment, it can quickly determine if the line is entirely inside, entirely outside, or needs further clipping. If clipping is needed, it iteratively clips the line against the boundaries of the clipping window.

Keywords: Cohen-Sutherland algorithm, line clipping, outcodes, clipping regions, boundary clipping.

Explain the Liang-Barsky Line Clipping Algorithm.

Answer: The Liang-Barsky algorithm is another line clipping

algorithm that is often more efficient than Cohen-Sutherland, especially for lines that are partially visible. It uses a parametric representation of the line and calculates the intersections with the clipping window's boundaries. It's particularly good at handling multiple clipping windows.

Keywords: Liang-Barsky algorithm, line clipping, parametric representation, clipping boundaries, efficiency.

What is Polygon Clipping? Name some algorithms.

Answer: Polygon clipping involves determining the portion of a polygon that lies within a clipping window. Algorithms like the Sutherland-Hodgman algorithm and the Weiler-Atherton algorithm are used for this purpose. The Sutherland-Hodgman algorithm clips a subject polygon against each edge of the clipping polygon sequentially.

Keywords: polygon clipping, Sutherland-Hodgman algorithm, Weiler-Atherton algorithm, clipping polygon, subject polygon.

V. 3D Viewing and Projection

This is where we move from 2D to the third dimension and how we represent it on a 2D screen.

What is a Projection in Computer Graphics?

Answer: Projection is the process of transforming 3D objects into 2D representations on a screen. It's how we create the illusion of depth on a flat surface.

Keywords: projection, 3D to 2D, perspective projection, orthographic projection, depth perception.

Explain Perspective Projection.

Answer: Perspective projection simulates how the human eye sees the world. Objects that are farther away appear smaller, and parallel lines converge at a vanishing point on the horizon. It creates a more realistic visual experience.

Keywords: perspective projection, vanishing point, realistic rendering, 3D perspective, field of view.

Explain Orthographic Projection.

Answer: Orthographic projection (also known as parallel projection) does not simulate the natural way of seeing. Lines do not converge, and objects maintain their size regardless of distance. This is commonly used in technical drawings, architectural plans, and some games for its clarity and lack of distortion.

Keywords: orthographic projection, parallel projection, technical drawing, architectural plans, no distortion.

What is a Viewport?

Answer: A viewport is a rectangular area on the screen where the projected image is displayed. It defines the boundaries on the display device for rendering the scene.

Keywords: viewport, screen area, rendering window, display boundaries.

What is the difference between a Viewport and a Window?

Answer:

1. **Window:** This refers to the part of the world coordinate system that we are interested in viewing. It's a conceptual area in the scene.
2. **Viewport:** This is the physical area on the screen (or another output device) where the contents of the window are displayed. It's the target area for rendering.

Keywords: window, viewport, world coordinates, screen coordinates, mapping, clipping window.

Explain the concepts of Normalized Device Coordinates (NDC).

Answer: Normalized Device Coordinates (NDC) are an intermediate coordinate system, typically ranging from -1 to 1 in

X and Y (and sometimes Z), that is used after the projection transformation and before the viewport transformation. This standardization makes it easier to map to different screen resolutions and devices.

Keywords: Normalized Device Coordinates, NDC, intermediate coordinates, projection space, device independence.

VI. Shading and Lighting

This is where we add realism to our 3D scenes.

What is Shading? Why is it important?

Answer: Shading is the process of calculating the color of each pixel on a surface to simulate how light interacts with it. It's crucial for creating realistic-looking 3D objects by adding depth, form, and texture to surfaces, making them appear three-dimensional and tangible.

Keywords: shading, surface illumination, realism, lighting models, pixel color.

Explain different types of shading models (e.g., Flat, Gouraud, Phong).

Answer:

1. **Flat Shading:** Calculates a single color for each polygon

based on the lighting at a single point (usually the polygon's normal). This results in faceted or blocky appearances.

2. **Gouraud Shading:** Interpolates colors across each polygon based on vertex colors. It calculates lighting at each vertex and then interpolates these colors across the polygon, providing a smoother appearance than flat shading.
3. **Phong Shading:** Interpolates surface normals across each polygon and then calculates lighting at each pixel. This results in very smooth and realistic highlights and shading, but it's computationally more expensive.

Keywords: flat shading, Gouraud shading, Phong shading, shading models, illumination, vertex colors, pixel interpolation.

What is Ambient Light, Diffuse Reflection, and Specular Reflection?

Answer: These are components of basic lighting models:

1. **Ambient Light:** A uniform, non-directional light that illuminates all surfaces equally. It simulates indirect lighting and prevents areas from being completely dark.
2. **Diffuse Reflection:** Light that bounces off a surface in all directions. The intensity of diffuse reflection depends on the angle between the light source and the surface normal (Lambert's cosine law). It gives surfaces their base color.
3. **Specular Reflection:** Light that reflects off a surface in a specific direction, creating highlights. This is most prominent

on shiny or glossy surfaces.

Keywords: ambient light, diffuse reflection, specular reflection, lighting components, Lambert's law, highlights.

Explain the concept of a light source.

Answer: A light source is an object or effect that emits light into the scene. In computer graphics, light sources are defined by their type (e.g., point, directional, spot), position, color, and intensity. They are fundamental to how objects are illuminated and rendered.

Keywords: light source, illumination, point light, directional light, spot light, intensity, color.

What is a normal vector? Why is it important?

Answer: A normal vector is a vector that is perpendicular to a surface at a given point. It's crucial for calculating how light interacts with the surface, as it determines the angle at which light hits the surface and reflects off it. Shading and lighting calculations heavily rely on normal vectors.

Keywords: normal vector, surface normal, perpendicular, lighting calculations, shading, surface orientation.

What are texture maps? How are they used?

Answer: Texture maps are images that are applied to the surfaces of 3D models to add detail, color, and surface properties without increasing the geometric complexity of the model. They are "wrapped" around the 3D object using UV coordinates. This allows for realistic rendering of materials like wood, brick, or fabric.

Keywords: texture maps, texture mapping, UV coordinates, surface detail, realism, materials.

VII. Advanced Topics & Miscellaneous

Be prepared for questions that delve into more specialized areas.

What is Ray Tracing?

Answer: Ray tracing is a rendering technique that simulates the physical behavior of light. It works by tracing the path of individual light rays from the camera into the scene, calculating their interactions with objects (reflection, refraction, absorption), and determining the color of each pixel. It can produce highly realistic images with accurate shadows and reflections but is computationally intensive.

Keywords: ray tracing, rendering technique, light rays, realism,

shadows, reflection, refraction.

What is the difference between Ray Tracing and Rasterization?

Answer:

1. **Rasterization:** Works by projecting 3D objects onto the 2D screen and then filling in the pixels. It's generally faster and is the dominant technique in real-time graphics like video games.
2. **Ray Tracing:** Works by simulating light rays. It's more physically accurate and excels at producing realistic global illumination, reflections, and shadows, but it's computationally more expensive and typically used for offline rendering (e.g., animated films).

Keywords: ray tracing vs rasterization, rendering methods, real-time graphics, offline rendering, performance, accuracy.

What is OpenGL?

Answer: OpenGL (Open Graphics Library) is a cross-language, cross-platform API (Application Programming Interface) for rendering 2D and 3D vector graphics. It's a set of functions that applications can use to interact with the graphics hardware. It's widely used in graphics programming.

Keywords: OpenGL, graphics API, cross-platform, rendering,

graphics programming.

What is DirectX?

Answer: DirectX is a collection of APIs developed by Microsoft for handling tasks related to multimedia, especially game programming and video, on Microsoft platforms. It includes components for graphics (Direct3D), sound (DirectSound), input devices, and networking.

Keywords: DirectX, Microsoft API, Direct3D, game development, multimedia.

Explain the rendering pipeline.

Answer: The rendering pipeline is a series of stages that a 3D model goes through from its raw data to its final display on the screen. It typically involves stages like vertex processing, geometry processing, rasterization, fragment processing, and output merging. Each stage performs specific transformations and calculations.

Keywords: rendering pipeline, graphics pipeline, vertex processing, rasterization, fragment shader, graphics stages.

What is anti-aliasing?

Answer: Anti-aliasing is a technique used to smooth out jagged edges (called "jaggies" or aliasing) that can appear in raster

graphics. It works by blending the colors of pixels along edges to create a smoother transition, making the image appear more realistic and less pixelated.

Keywords: anti-aliasing, jaggies, aliasing, image smoothing, pixelation.

What is Computer Vision? How does it relate to Computer Graphics?

Answer: Computer Vision is a field that enables computers to "see" and interpret the visual world. While Computer Graphics focuses on *generating* images, Computer Vision focuses on *analyzing* and *understanding* existing images or video. They are complementary: graphics can be used to generate training data for computer vision algorithms, and computer vision techniques can be used to reconstruct 3D scenes from images, which can then be rendered using graphics techniques.

Keywords: computer vision, image analysis, image generation, relationship, AI, machine learning.

Understanding the Core Concepts: The

Bedrock of Computer Graphics

Before diving into specific algorithms and techniques, it's essential to grasp the fundamental building blocks of computer graphics. These foundational questions often serve as icebreakers in a viva and reveal your basic comprehension.

What is Computer Graphics?

Answer: Computer graphics is a branch of computer science that deals with the generation, manipulation, and display of images and visual content using computers. It involves creating and processing visual representations of data, objects, and scenes. This encompasses a wide range of

applications, from scientific visualization and engineering design to entertainment and user interfaces. The core objective is to bridge the gap between abstract data and human perception, making complex information visually accessible and understandable.

What are the main components of a Computer Graphics System?

Answer: A typical computer graphics system comprises several key components:

- 1. Hardware: This includes the graphics processing unit (GPU) for accelerated computations, the monitor or display device for output, input devices like a**

mouse or tablet, and memory for storing image data and textures.

- 2. Software:** This involves graphics libraries (e.g., OpenGL, DirectX, Vulkan), graphics application programs (e.g., CAD software, game engines), and operating system graphics drivers.
- 3. Display Devices:** Devices like raster displays (CRT, LCD, LED) and vector displays (less common now) that render the generated images.
- 4. Input Devices:** Devices used to interact with the graphics system, such as keyboards, mice, joysticks, touchscreens, and specialized pointing devices.
- 5. Graphics Primitives:** The basic

graphical elements that can be drawn, such as points, lines, polygons, and curves.

Differentiate between Raster and Vector Graphics.

Answer: The fundamental difference lies in how images are stored and represented:

- 1. Raster Graphics: Images are composed of a grid of pixels (picture elements). Each pixel has a specific color value. Resolution-dependent, meaning quality degrades when scaled up. Examples include JPEGs, PNGs, and GIFs. Ideal for photographic images and complex scenes with subtle color gradients.**

2. Vector Graphics: Images are defined by mathematical equations that describe geometric primitives like lines, curves, and shapes. Resolution-independent, meaning they can be scaled infinitely without loss of quality. Examples include SVGs and AI files. Ideal for logos, illustrations, and diagrams where sharp edges and scalability are paramount.

The Magic of Transformations: Moving and Reshaping Objects

Transformations are the backbone of animation and manipulation in computer graphics. Understanding 2D and 3D transformations is crucial for manipulating objects in space.

2D Transformations

2D transformations allow us to manipulate objects in a two-dimensional plane. These include translation, rotation, and scaling.

What are the basic 2D transformations? Explain each with its transformation matrix.

Answer: The basic 2D transformations are:

- 1. Translation: Moving an object from one position to another. If an object is translated by T_x units in the x-direction and T_y units in the y-direction, the new coordinates (x', y') are given by:**

$$x' = x + T_x$$

$$y' = y + T_y$$

In homogeneous coordinates (using a 3x3 matrix), the transformation matrix is:

$$\begin{bmatrix} 1 & 0 & T_x \end{bmatrix}$$

$$\begin{bmatrix} 0 & 1 & T_y \end{bmatrix}$$

$$\begin{bmatrix} 0 & 0 & 1 \end{bmatrix}$$

2. Rotation: Rotating an object around a fixed point (usually the origin).

Rotating a point (x, y) by an angle θ counterclockwise around the origin results in (x', y'):

$$x' = x * \cos(\theta) - y * \sin(\theta)$$

$$y' = x * \sin(\theta) + y * \cos(\theta)$$

The transformation matrix is:

$$\begin{bmatrix} \cos(\theta) & -\sin(\theta) & 0 \\ \sin(\theta) & \cos(\theta) & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

3. Scaling: Enlarging or shrinking an object. Scaling by a factor S_x in the x-direction and S_y in the y-direction:

$$x' = x * S_x$$

$$y' = y * S_y$$

The transformation matrix is:

$$\begin{bmatrix} S_x & 0 & 0 \\ 0 & S_y & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

What is a composite transformation?

How is it achieved?

Answer: A composite transformation is

a sequence of multiple basic transformations applied to an object. For example, translating an object, then rotating it, and then scaling it. In 2D graphics, composite transformations are achieved by multiplying their respective transformation matrices. The order of multiplication is crucial, as matrix multiplication is not commutative. The combined transformation matrix represents the net effect of all individual transformations. This matrix multiplication is typically performed using homogeneous coordinates.

Explain the concept of Shearing.

Answer: Shearing is a transformation

that skews the shape of an object. In 2D, it can be applied along the x-axis or y-axis. For example, shearing along the x-axis by an amount Sh_x :

$$x' = x + Sh_x * y$$

$$y' = y$$

The transformation matrix for shearing along the x-axis is:

$$\begin{bmatrix} 1 & Sh_x & 0 \end{bmatrix}$$

$$\begin{bmatrix} 0 & 1 & 0 \end{bmatrix}$$

$$\begin{bmatrix} 0 & 0 & 1 \end{bmatrix}$$

A similar matrix exists for shearing along the y-axis.

3D Transformations

Extending 2D transformations to three dimensions involves adding

transformations along the z-axis and understanding new concepts like perspective projection.

What are the basic 3D transformations?

Answer: Similar to 2D, basic 3D transformations include:

- 1. Translation: Moving an object along the x, y, and z axes by T_x , T_y , and T_z respectively. The 4x4 homogeneous transformation matrix is:**

$$\begin{bmatrix} 1 & 0 & 0 & T_x \\ 0 & 1 & 0 & T_y \\ 0 & 0 & 1 & T_z \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

- 2. Rotation: Rotation can occur around**

the x, y, or z axes. For example, rotation around the z-axis by an angle θ :

$$\begin{bmatrix} \cos(\theta) & -\sin(\theta) & 0 & 0 \\ \sin(\theta) & \cos(\theta) & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

Matrices for rotation around x and y axes are also defined similarly.

3. Scaling: Scaling an object by factors S_x , S_y , and S_z along the respective axes. The transformation matrix is:

$$\begin{bmatrix} S_x & 0 & 0 & 0 \\ 0 & S_y & 0 & 0 \\ 0 & 0 & S_z & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

- 4. Reflection: Mirroring an object across a plane (e.g., the xy-plane).**
- 5. Shearing: Skewing in 3D, analogous to 2D shearing but can involve multiple axes.**

Explain the concept of a transformation pipeline.

Answer: The transformation pipeline, especially in 3D graphics, refers to a sequence of operations applied to geometric data (vertices) to transform them from object space to screen space. This typically involves:

- 1. Model Transformation: Transforms objects from their local coordinate system (model space) to world space.**
- 2. View Transformation: Transforms**

objects from world space to camera space (view space), effectively positioning and orienting the camera.

3. Projection Transformation:

Transforms objects from camera space into clip space. This includes perspective or orthographic projection, which defines how 3D objects are mapped to a 2D plane.

4. Viewport Transformation: Maps clip space coordinates to screen coordinates (pixel coordinates), defining the final position and size on the display.

Each stage can be represented by a transformation matrix, and these matrices are often concatenated to form a single transformation for efficiency.

What is the difference between Orthographic and Perspective Projection?

Answer:

- 1. Orthographic Projection: Parallel lines in 3D remain parallel in the 2D projection. Objects do not appear smaller as they get farther away. It preserves the actual size and shape of objects. Commonly used in technical drawings and CAD.**
- 2. Perspective Projection: Simulates how the human eye sees. Objects farther away appear smaller, and parallel lines converge at vanishing points. This creates a sense of depth and realism. It's essential for creating**

immersive 3D environments in games and simulations.

Clipping: Keeping What Matters, Discarding What Doesn't

Clipping algorithms are essential for efficiently rendering only the visible parts of a scene, improving performance and reducing processing load. Understanding clipping is vital for drawing operations.

Clipping Algorithms

What is Clipping? Why is it necessary?

Answer: Clipping is the process of identifying and discarding parts of a graphics primitive (like a line or polygon) that lie outside a specified

clipping window or region. It's necessary to:

- 1. Improve Efficiency: Avoid rendering objects or parts of objects that are not visible on the screen, saving computational resources.**
- 2. Define Visible Areas: Ensure that only the content within the defined display window is shown.**
- 3. Simplify Rendering: Reduce the complexity of the geometry that needs to be processed by subsequent rendering stages.**

Explain the Cohen-Sutherland Line Clipping Algorithm.

Answer: The Cohen-Sutherland algorithm is a line clipping algorithm

that divides the 2D space into nine regions based on the clipping window. Each region is assigned a 4-bit region code. The algorithm works as follows:

- 1. Assign Region Codes: For each endpoint of a line segment, determine its region code based on its position relative to the clipping window (top, bottom, left, right).**
- 2. Trivial Accept/Reject:**
 - 1. If both endpoints have region codes of 0000 (both inside the window), the entire line is trivially accepted.**
 - 2. If the bitwise AND of the region codes is not 0000 (meaning both endpoints are outside the window on the same side), the entire line is trivially rejected.**

3. Clipping: If neither trivial accept nor reject applies, the line segment is clipped. Choose an endpoint that is outside the window. Clip the line against the appropriate boundary (e.g., left boundary). Calculate the intersection point, replace the outside endpoint with this intersection point, update its region code, and repeat the process until the line is trivially accepted or rejected.

Explain the Liang-Barsky Line Clipping Algorithm.

Answer: The Liang-Barsky algorithm is another efficient line clipping algorithm, particularly suitable for parametric line representations and often preferred for

parametric clipping windows. For a line segment defined parametrically as $P(t) = P_1 + t(P_2 - P_1)$, where $0 \leq t \leq 1$, the algorithm derives inequalities based on the clipping window boundaries:

- 1. $x_1 + t \cdot dx \geq x_{min}$**
- 2. $x_1 + t \cdot dx \leq x_{max}$**
- 3. $y_1 + t \cdot dy \geq y_{min}$**
- 4. $y_1 + t \cdot dy \leq y_{max}$**

These inequalities are rewritten in the form $t \cdot p_k \leq q_k$. The algorithm calculates the range of t values (t_{enter} and t_{exit}) for which the line segment is inside the clipping window. If $t_{enter} > t_{exit}$, the line is rejected. Otherwise, the visible portion

of the line is drawn using the calculated t range.

What is Polygon Clipping?

Answer: Polygon clipping involves determining the portion of a polygon that lies within a specified clipping window. For convex polygons, algorithms like the Sutherland-Hodgman algorithm are commonly used. For concave polygons, more complex algorithms like Weiler-Atherton are employed. The Sutherland-Hodgman algorithm clips a polygon against each edge of the clipping window sequentially, outputting a new polygon after each clipping stage.

Rendering: Bringing Objects to Life

Rendering is the process of generating a 2D image from a 3D scene description. This involves complex algorithms for determining visibility, color, and lighting.

Rendering Techniques

What is the difference between a Painter's Algorithm and a Z-buffer Algorithm?

Answer: Both are depth-sorting algorithms used to solve the visibility problem (determining which surfaces are visible).

- 1. Painter's Algorithm: Sorts polygons based on their depth (typically front-**

to-back or back-to-front). It then renders the polygons in order, with polygons farther away being drawn first, and closer polygons overwriting them. Challenges include handling intersecting polygons and efficiently sorting.

2. Z-buffer (Depth Buffer) Algorithm: A frame buffer stores pixel color, and a corresponding Z-buffer stores the depth of the closest object at each pixel. As polygons are scanned, for each pixel, the depth of the fragment is compared with the value in the Z-buffer. If the new fragment is closer, its color and depth are updated in the frame buffer and Z-buffer, respectively. This is a more robust

and widely used approach for handling complex scenes and arbitrary geometry.

What are Shading Models? Explain different types of shading.

Answer: Shading models determine how light interacts with surfaces to produce realistic or stylized visual effects. They calculate the color of each pixel based on surface properties, light sources, and viewing direction. Common shading models include:

- 1. Flat Shading: Assigns a single color to an entire polygon. It's computationally inexpensive but results in a faceted appearance.**
- 2. Gouraud Shading: Calculates the**

illumination at the vertices of a polygon and interpolates these colors across the polygon. This produces smoother results than flat shading but can exhibit Mach bands (undesirable intensity transitions).

- 3. Phong Shading: Interpolates the surface normal across the polygon and calculates the illumination at each pixel based on the interpolated normal. This provides smoother highlights and more realistic lighting than Gouraud shading but is computationally more expensive.**

Explain the Phong Illumination Model.

Answer: The Phong illumination model (also known as the Phong reflection

model) is a widely used empirical model that describes how light reflects off a surface. It decomposes the total reflected light into three components:

- 1. Ambient Component: Represents indirect illumination, providing a base level of light to the scene, preventing completely black areas. It's a constant value added to all surfaces.**
- 2. Diffuse Component: Represents light scattered equally in all directions from a surface. It depends on the angle between the surface normal and the light source direction (Lambert's cosine law).**
- 3. Specular Component: Represents highlights on shiny surfaces. It depends on the angle between the**

view vector and the reflection vector of the light. This component gives surfaces a lustrous appearance.

The sum of these components, modulated by the surface's color and light intensity, determines the final pixel color.

What is Ray Tracing?

Answer: Ray tracing is a rendering technique that simulates the physical behavior of light. It works by casting rays from the camera through each pixel into the scene. When a ray intersects an object, secondary rays are cast to simulate reflections, refractions, and shadows. This process recursively continues until the rays no longer

intersect objects or reach a maximum depth. Ray tracing produces highly realistic images with accurate shadows, reflections, and refractions but is computationally intensive.

What is Texture Mapping?

Answer: Texture mapping is a technique used to add detail, realism, and surface complexity to 3D models without increasing the geometric complexity. It involves applying a 2D image (a texture) onto the surface of a 3D object. Texture coordinates (UV coordinates) are used to map points on the 2D texture to points on the 3D surface. This can be used for anything from wood grain and brick patterns to complex characters

and abstract designs.

Fundamental Graphics Algorithms

Beyond transformations and rendering, several fundamental algorithms are core to computer graphics.

Explain Bresenham's Line Drawing Algorithm.

Answer: Bresenham's Line Drawing Algorithm is an efficient algorithm for drawing lines on a raster display. It uses only integer arithmetic and simple decision parameters to determine which pixel to illuminate next, minimizing computational overhead. The algorithm iteratively decides whether to move horizontally, vertically, or diagonally to

stay as close as possible to the ideal line path. It's widely used due to its speed and accuracy.

What is Flood Fill Algorithm?

Answer: The Flood Fill Algorithm is used to fill a connected region of a multi-dimensional array (like an image) with a specified color. Starting from a seed point, it recursively or iteratively fills adjacent pixels that have the same initial color as the seed point. Two common approaches are 4-connectivity (filling up, down, left, right) and 8-connectivity (including diagonals). It's often used in painting programs for filling areas.

Explain the Midpoint Circle Algorithm.

Answer: The Midpoint Circle Algorithm is an efficient method for drawing circles on a raster display. Similar to Bresenham's line algorithm, it uses decision parameters to determine which pixel is closest to the ideal circle path. It calculates points in one octant (1/8th of the circle) and then uses symmetry to generate points for the remaining seven octants, reducing the number of calculations needed.

Advanced Concepts and Future Trends

While core concepts are crucial, understanding broader trends in computer graphics can demonstrate a forward-thinking approach.

What are some common applications of Computer Graphics?

- 1. Entertainment: Video games, animated films, special effects in movies.**
- 2. Design and Engineering: CAD (Computer-Aided Design), architectural visualization, product design, simulations.**
- 3. Medical Imaging: MRI, CT scans, visualization of anatomical structures.**
- 4. Scientific Visualization: Representing complex data sets (e.g., weather patterns, molecular structures).**
- 5. User Interfaces: Graphical User Interfaces (GUIs) for operating**

systems and applications.

- 6. Virtual Reality (VR) and Augmented Reality (AR): Immersive experiences and overlaying digital information onto the real world.**

What is the role of the GPU in modern computer graphics?

Answer: The Graphics Processing Unit (GPU) is a specialized processor designed for parallel computation, making it incredibly efficient at handling the massive amounts of calculations required for rendering complex graphics. It accelerates tasks like vertex processing, pixel shading, texture mapping, and rasterization. Modern GPUs are essential for real-time

graphics in games, high-performance computing, and AI applications.

- 1. Real-time Ray Tracing: Achieving photorealistic lighting and reflections in real-time, especially in games.**
- 2. AI and Machine Learning in Graphics: Using AI for tasks like content generation, super-resolution, denoising, and character animation.**
- 3. Volumetric Rendering: Rendering complex phenomena like smoke, fire, and clouds more realistically.**

Questions & Answers About computer graphics viva questions and answers for mca

N o	Question	Answer
1	Can you explain the difference between raster and vector graphics and when you'd use each?	Raster graphics (like JPEGs, PNGs) are made of pixels and are great for photos and complex imagery. They lose quality when scaled up. Vector graphics (like SVGs, AI) use mathematical equations and are ideal for logos, icons, and illustrations as they can be scaled infinitely without quality loss. You'd use raster for photos, and vector for scalable designs.

2	What's the role of the graphics pipeline, and what are its main stages?	The graphics pipeline is a series of steps that a 3D model goes through to be rendered into a 2D image on your screen. Key stages include: 1. Application stage (CPU), 2. Geometry stage (GPU - vertex processing, tessellation), 3. Rasterization stage (GPU - converting geometry to pixels), and 4. Fragment stage (GPU - pixel processing, texturing, lighting, depth testing, blending).
3	How does lighting work in computer graphics, and what are some common lighting models?	Lighting simulates how light interacts with surfaces to create realism. Common models include: 1. Ambient Lighting (uniform light from all directions), 2. Diffuse Lighting (light scattering equally from a surface), and 3. Specular Lighting (highlights or shininess on surfaces). More advanced models like Phong and Blinn-Phong combine these.
4	Explain texture mapping. What are mipmaps and why are they important?	Texture mapping is the process of applying a 2D image (texture) onto a 3D model's surface to add detail. Mipmaps are pre-calculated, smaller versions of a texture. They are crucial for reducing aliasing (jagged edges) and improving performance when objects are far away by using a lower-resolution mipmap instead of the full texture.

5	What is aliasing in computer graphics, and what techniques are used to mitigate it?	Aliasing refers to jagged or stair-stepped edges that appear when representing smooth curves or lines with discrete pixels. Anti-aliasing techniques, like supersampling (sampling more pixels than displayed) and multisampling (sampling corners of pixels), are used to smooth these edges and create a more visually pleasing image.
6	Can you describe the concept of shaders and their importance in modern graphics?	Shaders are small programs that run on the GPU to control how surfaces are rendered. They define visual properties like color, lighting, and textures. Vertex shaders manipulate vertex data (position, color), while fragment (or pixel) shaders determine the final color of each pixel. They are vital for achieving complex visual effects and realism.
7	What is a transformation matrix, and what are the common types of transformations?	A transformation matrix is a mathematical tool used to perform geometric transformations on objects (vertices). Common transformations include: 1. Translation (moving an object), 2. Rotation (turning an object), and 3. Scaling (resizing an object). These matrices are multiplied with vertex coordinates to achieve the desired effect.

8	How does hidden surface removal work? What are some popular algorithms?	Hidden surface removal (or occlusion culling) is the process of determining which parts of a 3D scene are not visible to the camera and should not be rendered. Popular algorithms include: 1. Z-buffer (depth buffer) algorithm, which stores the depth of the closest object for each pixel, and 2. Painter's algorithm, which sorts polygons by depth and draws them from back to front.
9	What is ray tracing, and how does it differ from rasterization?	Ray tracing simulates light rays bouncing through a scene, calculating their interactions with objects to create photorealistic images. It naturally handles complex lighting, reflections, and refractions. Rasterization, on the other hand, projects 3D geometry onto a 2D screen and fills in pixels, generally being faster but requiring more manual techniques for advanced lighting effects.
10	Explain the concept of normal vectors and their significance in rendering.	Normal vectors are vectors perpendicular to a surface at a specific point. They are crucial for determining how light interacts with that surface. When rendering, the direction of the normal vector influences how light is reflected (diffuse and specular components), and thus greatly affects the perceived shading and lighting of an object.
