Mastering Chemical Quantities: A Comprehensive Study Guide

Chemistry revolves around the study of matter and its transformations. Understanding chemical quantities is fundamental to grasping the underlying principles and applying them to real-world scenarios. This guide delves into the essential concepts and techniques of chemical quantities, equipping you with the tools to excel in your studies.

1. Fundamental Concepts: Building the Foundation

Before embarking on calculations, a solid understanding of key concepts is crucial.

a) The Mole (mol): The Chemist's Counting Unit The mole is the SI unit for the amount of substance, analogous to a "dozen" for everyday objects. One mole of any substance contains **6.022×10^{23}** particles, known as Avogadro's number. **Example:** One mole of carbon atoms (C) contains 6.022×10^{23} carbon atoms.

b) Molar Mass (g/mol): Connecting Mass and Moles The molar mass of a substance is the mass of one mole of that substance. It's numerically equal to the atomic or molecular weight of the substance expressed in grams. *Example:* The molar mass of carbon (C) is 12.01 g/mol. This means 1 mole of carbon atoms weighs 12.01 grams.

c) Chemical Formulas and Stoichiometry Chemical formulas represent the composition of a substance, indicating the types and number of atoms present. Stoichiometry refers to the quantitative

relationships between reactants and products in a chemical reaction, governed by the law of conservation of mass. **Example:** The balanced chemical equation for the combustion of methane is: $\text{CH}_4 + 2\text{O}_2 \rightarrow \text{CO}_2 + 2\text{H}_2\text{O}$ This equation tells us that one mole of methane reacts with two moles of oxygen to produce one mole of carbon dioxide and two moles of water.

2. Calculating Chemical Quantities: Essential Techniques

Armed with the fundamental concepts, we can tackle practical calculations involving chemical quantities. *a) Converting Between Grams, Moles, and Number of Ps*

- **Grams to Moles:** Divide the mass in grams by the molar mass.
- **Moles to Grams:** Multiply the number of moles by the molar mass.
- **Moles to Number of Ps:** Multiply the number of moles by Avogadro's number.
- **Number of Ps to Moles:** Divide the number of ps by Avogadro's number. *Example:* How many moles of sodium chloride (NaCl) are present in 10 grams of NaCl? Molar mass of NaCl = 58.44 g/mol Moles of NaCl = Mass of NaCl / Molar mass of NaCl = 10 g / 58.44 g/mol = 0.171 moles

b) Stoichiometry Calculations:

Predicting Reaction Yields Stoichiometry allows us to predict the amount of reactants needed or products formed in a given reaction.

- **Mole-to-Mole Conversions:** Use the coefficients in a balanced chemical equation to relate the number of moles of reactants and products.
- **Grams-to-Grams Conversions:** Convert grams to moles, use mole ratios from the balanced equation, and then convert moles back to grams. *Example:* How many grams of carbon dioxide (CO₂) are produced from the complete combustion of 5 grams of methane (CH₄)? Balanced equation: $\text{CH}_4 + 2\text{O}_2 \rightarrow \text{CO}_2 + 2\text{H}_2\text{O}$ Molar mass of CH₄ = 16.04 g/mol Molar mass of CO₂ = 44.01 g/mol

- 1) Convert grams of CH₄ to moles: 5 g / 16.04 g/mol = 0.312 moles CH₄
- 2) Use mole ratio from the balanced equation: 0.312 moles CH₄ x (1 mole CO₂ / 1 mole CH₄) = 0.312 moles CO₂
- 3) Convert moles of CO₂ to grams: 0.312 moles CO₂ x 44.01 g/mol = 13.73 g CO₂

c) Limiting Reactants and Percent Yield

Limiting Reactant: The reactant that is completely consumed first in a reaction, limiting the amount of product formed.

Percent Yield: The ratio of actual yield (experimentally

obtained) to theoretical yield (calculated stoichiometrically), expressed as a percentage. **Example:** If 10 grams of sodium (Na) reacts with 15 grams of chlorine (Cl₂), what is the limiting reactant and the theoretical yield of sodium chloride (NaCl)? Balanced equation: $2\text{Na} + \text{Cl}_2 \rightarrow 2\text{NaCl}$ Molar mass of Na = 22.99 g/mol Molar mass of Cl₂ = 70.90 g/mol Molar mass of NaCl = 58.44 g/mol

1) Calculate moles of each reactant: - Moles of Na = $10 \text{ g} / 22.99 \text{ g/mol} = 0.435$ moles - Moles of Cl₂ = $15 \text{ g} / 70.90 \text{ g/mol} = 0.212$ moles 2) Determine the limiting reactant: - Na: $0.435 \text{ moles Na} \times (1 \text{ mole Cl}_2 / 2 \text{ moles Na}) = 0.2175$ moles Cl₂ needed - Since we have less Cl₂ (0.212 moles) than needed (0.2175 moles), Cl₂ is the limiting reactant. 3) Calculate the theoretical yield of NaCl: - $0.212 \text{ moles Cl}_2 \times (2 \text{ moles NaCl} / 1 \text{ mole Cl}_2) = 0.424$ moles NaCl - $0.424 \text{ moles NaCl} \times 58.44 \text{ g/mol} = 24.78 \text{ g NaCl}$ **d) Solution Concentration:**

Expressing the Amount of Solute Solutions are homogeneous mixtures containing a solute dissolved in a solvent. Concentration expresses the amount of solute present in a given amount of solution. • **Molarity (M):** Moles of solute per liter of solution. • **Molality (m):** Moles of solute per kilogram of solvent.

Example: A 0.5 M solution of glucose (C₆H₁₂O₆) contains 0.5 moles of glucose dissolved in 1 liter of solution. **e) Dilution: Changing Solution Concentration**

Dilution involves adding more solvent to a solution, decreasing its concentration.

• **$M_1V_1 = M_2V_2$:** Where M₁ and V₁ are the initial molarity and volume, and M₂ and V₂ are the final molarity and volume. **Example:** To prepare 250 mL of a 0.2 M NaCl solution from a 1 M stock solution, we can use the dilution formula: $M_1V_1 = M_2V_2$ $1 \text{ M} \times V_1 = 0.2 \text{ M} \times 250 \text{ mL}$ $V_1 = 50 \text{ mL}$ We would take 50 mL of the 1 M stock solution and dilute it with water to a final volume of 250 mL.

3. Common Pitfalls to Avoid: Ensuring Accuracy in Calculations

While mastering chemical quantities is rewarding, certain pitfalls can lead to errors. Here are common mistakes to watch out for: • **Incorrectly Balancing Chemical Equations:** A balanced equation is crucial for accurate stoichiometry calculations. Ensure that the number of atoms of each element is equal on both sides of the equation. • **Misinterpreting Units:** Always carefully consider the units

involved in calculations. Misinterpreting grams for moles or liters for milliliters can lead to significant errors. • **Incorrect Use of Limiting Reactants:** When multiple reactants are involved, correctly identifying the limiting reactant is essential for determining the theoretical yield. • **Not Accounting for Density in Dilution:** The density of the solution can impact the final volume. Avoid assuming the volume of the solution is equal to the volume of the solvent added.

4. Best Practices for Success

- **Practice Regularly:** Frequent practice is key to mastering chemical quantities. Work through textbook problems, sample questions, and past exam papers.
- **Organize Your Work:** Maintain clear and organized calculations, showing all steps and units to prevent confusion.
- **Visualize Concepts:** Use diagrams and models to visualize abstract concepts like moles and stoichiometry.
- **Seek Help When Needed:** Don't hesitate to ask your teacher, classmates, or tutors for clarification if you encounter difficulties.
- **Develop a Strong Foundation:** Before diving into complex calculations, ensure a thorough understanding of the fundamental concepts.

5. Key Takeaways

This study guide is designed to break down the seemingly complex topic of chemical quantities into digestible, understandable chunks. We'll explore the essential building blocks, from the humble atom to the mighty mole, and equip you with the knowledge to confidently tackle stoichiometry, molar mass, and all those exciting calculations. So, grab your metaphorical lab coat, and let's dive into the fascinating realm of chemistry's quantities!

The Building Blocks: Atoms, Molecules,

and Ions

Before we can talk about quantities, we need to understand what we're quantifying. At the heart of everything chemical are atoms – the tiny, fundamental particles of matter. These aren't just abstract ideas; they're the real deal, the LEGO bricks of the universe. Atoms are composed of even smaller subatomic particles: protons (positive charge), neutrons (no charge), and electrons (negative charge).

Atoms: The Basics

The number of protons in an atom's nucleus defines the element. This is its atomic number. For example, every atom with 6 protons is a carbon atom. Atoms of the same element can have different numbers of neutrons, which are called isotopes. While isotopes of an element behave chemically in very similar ways, their masses differ. When we talk about the mass of an atom, we often refer to its atomic mass, which is typically expressed in atomic mass units (amu). This value is usually an average of the masses of its naturally occurring isotopes.

Molecules: When Atoms Unite

Atoms rarely exist in isolation. They love to bond together to form molecules. A molecule is a group of two or more atoms held together by chemical bonds. Think of water (H_2O) – it's two hydrogen atoms bonded to one oxygen atom. The chemical formula tells us not only which atoms are present but also in what proportion. This is crucial when we start thinking about quantities. For instance, in a molecule of water, there are always two hydrogen atoms for every one oxygen atom.

Ions: Charged Particles

Sometimes, atoms or groups of atoms can gain or lose electrons, resulting in a net electrical charge. These charged species are called ions. Positively charged ions are cations (e.g., Na^+), and negatively charged ions are anions (e.g., Cl^-). These charged particles play vital roles in many chemical reactions and are the basis of ionic compounds, like table salt (NaCl).

Measuring the Immeasurable: The Mole Concept

Now, here's where things get really interesting. We can't possibly count individual atoms or molecules; they are far too small. Imagine trying to count every grain of sand on a beach – it's an impossible task. So, chemists developed a way to group atoms and molecules into manageable "counting units." This unit is the mole.

What is a Mole?

A mole is simply a very, very large number. It's analogous to how a "dozen" means 12 of something, or a "gross" means 144. A mole, however, represents a staggering 6.022×10^{23} particles. This specific number is known as Avogadro's number (N_A). So, one mole of carbon atoms contains 6.022×10^{23} carbon atoms, and one mole of water molecules contains 6.022×10^{23} water molecules.

Why Avogadro's Number?

Avogadro's number isn't arbitrary. It was chosen because it directly relates the mass of a substance in grams to the number of particles in moles. Specifically, one mole of any element has a mass in grams equal to its atomic mass in atomic mass units (amu). For example, the atomic mass of carbon is approximately 12.01 amu. Therefore, one mole of carbon atoms weighs approximately 12.01

grams. This incredible convenience is what makes the mole concept so powerful in chemistry.

Connecting Mass and Moles: Molar Mass

The bridge between the mass of a substance and the number of moles it contains is called molar mass. The molar mass of a pure substance is defined as the mass of one mole of that substance. For elements, the molar mass is numerically equal to the atomic mass found on the periodic table, but it's expressed in grams per mole (g/mol).

For compounds, the molar mass is calculated by summing the molar masses of all the atoms in the chemical formula. Let's take water (H₂O) again:

1. Molar mass of Hydrogen (H) $\approx$ 1.01 g/mol
2. Molar mass of Oxygen (O) $\approx$ 16.00 g/mol
3. Molar mass of H₂O = (2 x molar mass of H) + (1 x molar mass of O)
4. Molar mass of H₂O = (2 x 1.01 g/mol) + (1 x 16.00 g/mol) = 2.02 g/mol + 16.00 g/mol = 18.02 g/mol

This means that 18.02 grams of water contains one mole of water molecules, which is 6.022×10^{23} water molecules.

Stoichiometry: The Art of Chemical Calculation

Now that we have the tools to quantify atoms and molecules, we can delve into stoichiometry. This is the branch of chemistry that deals with the quantitative relationships between reactants and products in chemical reactions. It's essentially about balancing the books in a chemical reaction – ensuring that no atoms are created or destroyed.

Balanced Chemical Equations: The Foundation

The first and most critical step in stoichiometry is to have a correctly balanced chemical equation. A balanced equation reflects the law of conservation of mass, meaning that the number of atoms of each element must be the same on both the reactant side (left side) and the product side (right side) of the equation. Coefficients are used to balance the equations. These coefficients represent the molar ratios of the reactants and products.

For example, the combustion of methane (natural gas) is:

In this equation:

1. One molecule (or mole) of methane reacts with two molecules (or moles) of oxygen.
2. This produces one molecule (or mole) of carbon dioxide and two molecules (or moles) of water.

The coefficients (1, 2, 1, 2) tell us the molar ratios. This is the key to stoichiometric calculations.

Mole Ratios: The Currency of Reactions

The coefficients in a balanced chemical equation are used to determine the mole ratios between different substances in the reaction. These mole ratios act as conversion factors to relate the amount of one substance to the amount of another.

Using our methane combustion example:

1. The mole ratio of CH_4 to O_2 is 1:2. For every 1 mole of CH_4 reacted, 2 moles of O_2 are consumed.
2. The mole ratio of CH_4 to CO_2 is 1:1. For every 1 mole of CH_4 reacted, 1 mole

of CO_2 is produced.

3. The mole ratio of O_2 to H_2O is 2:2 (or 1:1). For every 2 moles of O_2 consumed, 2 moles of H_2O are produced.

Solving Stoichiometry Problems

Stoichiometry problems typically involve calculating the amount of a product formed from a given amount of a reactant, or vice versa. The general strategy involves these steps:

1. **Write and balance the chemical equation.** This is your roadmap.
2. **Convert the given amount of the known substance to moles.** If you're given mass, use molar mass. If you're given volume of a gas at STP (Standard Temperature and Pressure), use the molar volume (22.4 L/mol).
3. **Use the mole ratio from the balanced equation to convert moles of the known substance to moles of the unknown substance.**
4. **Convert moles of the unknown substance to the desired units.** If you need mass, use its molar mass. If it's a gas, you might need to consider its volume.

Limiting Reactants: The Scarcity Factor

In a real-world reaction, you rarely have the exact stoichiometric amounts of all reactants. Usually, one reactant will be completely consumed before the others. This reactant is called the **limiting reactant** (or limiting reagent). It determines the maximum amount of product that can be formed because once it's used up, the reaction stops.

The other reactants that are not completely used up are called **excess reactants**. To identify the limiting reactant:

1. Calculate the amount of product that **could** be formed from each reactant, assuming the other reactant is in excess.
2. The reactant that produces the **least** amount of product is the limiting

reactant.

Percent Yield: Measuring Efficiency

In chemistry, the amount of product we calculate using stoichiometry is called the **theoretical yield** – the maximum possible amount of product that can be obtained. However, in practice, the actual amount of product obtained in a laboratory experiment is often less than the theoretical yield. This is due to various factors like incomplete reactions, side reactions, or loss of product during purification.

The **actual yield** is the amount of product experimentally determined. The **percent yield** is a measure of the efficiency of a reaction and is calculated as:

$$\text{Percent Yield} = (\text{Actual Yield} / \text{Theoretical Yield}) \times 100\%$$

Key Quantities in Chemistry: A Summary

Let's quickly recap the essential quantities we've covered:

1. **Atomic Mass Unit (amu):** A unit of mass used to express atomic and molecular weights, approximately the mass of a single proton or neutron.

4. **Molar Mass (g/mol):** The mass of one mole of a substance. It's numerically equal to the atomic or molecular weight in amu.
5. **Stoichiometry:** The quantitative study of reactants and products in chemical reactions, based on the law of conservation of mass.
6. **Mole Ratio:** The ratio of coefficients of substances in a balanced chemical

equation, used as a conversion factor in stoichiometric calculations.

Why are Chemical Quantities So Important?

The study of chemistry is inherently quantitative. From synthesizing new drugs to understanding atmospheric pollution, chemists rely on precise measurements and calculations. Chemical quantities allow us to:

1. **Predict reaction yields:** How much product can we expect from a given amount of reactants?
2. **Control reactions:** Ensuring the correct stoichiometry is crucial for efficient and safe chemical processes.

3. **Analyze substances:** Determining the composition and purity of unknown samples.
4. **Understand physical properties:** Properties like density and molarity are directly related to the amount of substance present.

The Mole: The Cornerstone of Chemical Quantities

At the heart of chemical quantities lies the **mole**. Often described as a chemist's dozen, the mole is a unit of amount that represents a specific number of particles. This number, Avogadro's number, is approximately 6.022×10^{23} . This means one mole of any substance contains 6.022×10^{23} entities (atoms, molecules, ions, etc.).

Avogadro's Number and its Significance

Avogadro's number provides a bridge between the microscopic world of atoms and molecules and the macroscopic world we can measure. It allows us to relate the mass of a substance (which we can weigh) to the number of particles it contains (which we can't directly count).

Molar Mass: Connecting Mass and Moles

The **molar mass** of a substance is the mass of one mole of that substance, typically expressed in grams per mole (g/mol). This value is numerically equal to the atomic or molecular weight of the substance found on the periodic table. For elements, it's the atomic mass; for compounds, it's the sum of the atomic masses of all the atoms in the molecule. For example:

1. The molar mass of Carbon (C) is approximately 12.01 g/mol.
2. The molar mass of Water (H_2O) is $(2 \times 1.01 \text{ g/mol for Hydrogen}) + (16.00 \text{ g/mol for Oxygen}) = 18.02 \text{ g/mol}$.

The relationship between mass, moles, and molar mass is fundamental:

$$\text{Moles} = \text{Mass (g)} / \text{Molar Mass (g/mol)}$$

$$\text{Mass (g)} = \text{Moles} \times \text{Molar Mass (g/mol)}$$

Calculating Moles from Mass and Vice Versa

Let's illustrate with an example. If you have 50.0 grams of sodium chloride (NaCl), how many moles of NaCl do you have?

First, find the molar mass of NaCl: Na (22.99 g/mol) + Cl (35.45 g/mol) = 58.44 g/mol.

$$\text{Moles of NaCl} = 50.0 \text{ g} / 58.44 \text{ g/mol} = 0.856 \text{ mol.}$$

Conversely, if you need 2.5 moles of sulfuric acid (H₂SO₄), how many grams is that?

$$\text{Molar mass of H}_2\text{SO}_4 = (2 \times 1.01 \text{ g/mol}) + 32.07 \text{ g/mol} + (4 \times 16.00 \text{ g/mol}) = 98.09 \text{ g/mol.}$$

$$\text{Mass of H}_2\text{SO}_4 = 2.5 \text{ mol} \times 98.09 \text{ g/mol} = 245.23 \text{ g.}$$

Stoichiometry: The Art of Chemical Calculations

Stoichiometry is the branch of chemistry that deals with the quantitative relationships between reactants and products in chemical reactions. It's essentially using chemical equations to predict how much of one substance will be consumed or produced in a reaction. The foundation of stoichiometry is the **balanced chemical equation**.

The Importance of Balanced Chemical Equations

A balanced chemical equation follows the law of conservation of mass, meaning the number of atoms of each element must be the same on both sides of the

equation. Coefficients in front of the chemical formulas represent the molar ratios of the substances involved.

For example, the combustion of methane:

This equation tells us that 1 mole of methane reacts with 2 moles of oxygen to produce 1 mole of carbon dioxide and 2 moles of water. These molar ratios are crucial for stoichiometric calculations.

Mole-to-Mole Conversions

Using the balanced equation, we can convert moles of one substance to moles of another. If we have 3 moles of methane, how many moles of oxygen are needed for complete combustion?

From the equation, the ratio is 1 mol CH_4 : 2 mol O_2 .

Moles of O_2 = 3 mol CH_4 x (2 mol O_2 / 1 mol CH_4) = 6 mol O_2 .

Mass-to-Mass Stoichiometry: The Three-Step Process

Most real-world stoichiometric problems involve converting between the masses of different substances. This is a three-step process:

1. **Convert the mass of the given substance to moles** using its molar mass.
2. **Convert moles of the given substance to moles of the desired substance** using the mole ratios from the balanced chemical equation.
3. **Convert moles of the desired substance to mass** using its molar mass.

Let's use the methane combustion example again. If we start with 16.0 grams of methane, how many grams of water are produced?

Molar mass of CH_4 = 12.01 + (4 x 1.01) = 16.05 g/mol.

Molar mass of H_2O = 18.02 g/mol.

Step 1: Moles of $\text{CH}_4 = 16.0 \text{ g} / 16.05 \text{ g/mol} = 0.997 \text{ mol}$.

Step 2: Moles of $\text{H}_2\text{O} = 0.997 \text{ mol CH}_4 \times (2 \text{ mol H}_2\text{O} / 1 \text{ mol CH}_4) = 1.994 \text{ mol H}_2\text{O}$.

Step 3: Mass of $\text{H}_2\text{O} = 1.994 \text{ mol} \times 18.02 \text{ g/mol} = 35.93 \text{ g}$.

Limiting Reactants and Percent Yield

In many reactions, one reactant is completely consumed before the others. This reactant is called the **limiting reactant**, as it determines the maximum amount of product that can be formed. The other reactants are in excess.

Percent yield is a measure of the efficiency of a reaction. It is calculated as:

$$\text{Percent Yield} = (\text{Actual Yield} / \text{Theoretical Yield}) \times 100\%$$

The **theoretical yield** is the maximum amount of product that can be formed, calculated using stoichiometry. The **actual yield** is the amount of product actually obtained in the laboratory, which is often less than the theoretical yield due to factors like incomplete reactions or side reactions.

Concentration: Quantifying Solutions

When substances are dissolved in a solvent, they form solutions.

Concentration describes the amount of solute present in a given amount of solution or solvent. Understanding solution concentration is vital in analytical chemistry, biochemistry, and many industrial processes.

Molarity: The Most Common Concentration Unit

Molarity (M) is defined as the number of moles of solute per liter of solution.

$$\text{Molarity (M)} = \text{Moles of Solute} / \text{Liters of Solution}$$

For example, a 0.5 M NaCl solution contains 0.5 moles of NaCl dissolved in enough water to make 1 liter of solution.

Calculating Molarity

To prepare a solution of a specific molarity, you need to calculate the mass of solute required. For instance, to make 500 mL (0.5 L) of a 0.1 M copper(II) sulfate (CuSO_4) solution:

First, calculate the moles of CuSO_4 needed: $\text{Moles} = \text{Molarity} \times \text{Liters} = 0.1 \text{ mol/L} \times 0.5 \text{ L} = 0.05 \text{ mol}$.

Next, find the molar mass of CuSO_4 : $\text{Cu} (63.55 \text{ g/mol}) + \text{S} (32.07 \text{ g/mol}) + 4 \times \text{O} (16.00 \text{ g/mol}) = 159.62 \text{ g/mol}$.

Finally, calculate the mass of CuSO_4 : $\text{Mass} = \text{Moles} \times \text{Molar Mass} = 0.05 \text{ mol} \times 159.62 \text{ g/mol} = 7.98 \text{ g}$. You would weigh out 7.98 grams of CuSO_4 and dissolve it in enough water to make a final volume of 500 mL.

Dilution Calculations

Dilution is the process of reducing the concentration of a solute in a solution by adding more solvent. The amount of solute remains constant, but the volume of the solution increases, thus decreasing the concentration.

The dilution equation is: $M_1V_1 = M_2V_2$

Where:

1. M_1 is the initial molarity
2. V_1 is the initial volume
3. M_2 is the final molarity
4. V_2 is the final volume

If you have 100 mL of a 2.0 M HCl solution and you dilute it to a final volume of 500 mL, what is the new concentration?

$$(2.0 \text{ M}) \times (100 \text{ mL}) = M_2 \times (500 \text{ mL})$$

$$M_2 = (2.0 \text{ M} \times 100 \text{ mL}) / 500 \text{ mL} = 0.4 \text{ M}.$$

Other Important Units and Concepts

While the mole and molarity are central, several other quantitative units and concepts are essential for a complete understanding.

Percent Composition by Mass

Percent composition by mass expresses the percentage by mass of each element in a compound. It's calculated by dividing the total mass of the element in one mole of the compound by the molar mass of the compound and multiplying by 100%.

Parts Per Million (ppm) and Parts Per Billion (ppb)

These units are commonly used for very dilute solutions, especially in environmental science and toxicology. They represent the mass of solute per million or billion units of mass of the solution, respectively.

Gas Laws and Molar Volume

For gases, the **ideal gas law** ($PV = nRT$) connects pressure (P), volume (V), moles (n), the ideal gas constant (R), and temperature (T). At standard temperature and pressure (STP), one mole of any ideal gas occupies approximately 22.4 liters of volume. This **molar volume** at STP is a crucial conversion factor for gas stoichiometry.

Tips for Success in Studying Chemical Quantities

Questions & Answers About chemistry chemical quantities study guide

No	Question	Answer
----	----------	--------

1	What's the big deal with 'moles' in chemistry, and how do I calculate them?	The mole (mol) is the SI unit for amount of substance, representing a specific number of particles (Avogadro's number, 6.022×10^{23}). You calculate moles by dividing the mass of a substance by its molar mass (found on the periodic table) or by dividing the number of particles by Avogadro's number.
2	How can I use molar mass to convert between grams and moles?	Molar mass is your bridge! To convert grams to moles, divide the mass (in grams) by the molar mass (in g/mol). To convert moles to grams, multiply the moles by the molar mass.
3	What's the difference between empirical and molecular formulas, and why should I care?	The empirical formula shows the simplest whole-number ratio of atoms in a compound, while the molecular formula shows the actual number of atoms. You need the empirical formula to find the molecular formula when you know the compound's molar mass.
4	Stoichiometry sounds scary! How can I simplify calculations involving chemical reactions?	Stoichiometry uses balanced chemical equations to relate the amounts of reactants and products. The key is the mole ratio between substances in the balanced equation. You'll often convert a given quantity to moles, use the mole ratio, and then convert back to the desired unit.
5	What are limiting and excess reactants, and how do I identify them?	The limiting reactant is completely consumed in a reaction and determines the maximum amount of product formed. The excess reactant is left over. To identify the limiting reactant, calculate how much product each reactant <i>could</i> produce; the one that produces less is the limiting one.
6	What is percent yield, and why is it often less than 100%?	Percent yield compares the actual amount of product obtained in an experiment to the theoretical yield (the maximum possible amount calculated from stoichiometry). It's usually less than 100% due to side reactions, incomplete reactions, or product loss during purification.

7	How do I deal with solutions and concentrations like molarity in my calculations?	Molarity (M) is a common unit of concentration, defined as moles of solute per liter of solution (mol/L). To use it, you can rearrange the formula to find moles of solute ($M \times V$) or volume of solution (moles / M). This is crucial for solution stoichiometry.
