

How to do algebra word problems

Unlocking the Secrets of Algebra Word Problems: A Practical Guide Have you ever stared blankly at a word problem, feeling utterly lost in a sea of confusing sentences and unknown variables? Algebra word problems, while seemingly daunting, are actually a gateway to understanding the world around us. They're not about memorizing formulas; they're about applying your mathematical knowledge to real-life scenarios. This comprehensive guide will equip you with the tools and techniques to tackle these challenges with confidence. *Decoding the Language of Word Problems* The first hurdle in solving algebra word problems is translating the words into mathematical expressions. This often requires identifying key phrases and understanding their corresponding mathematical operations. A thorough understanding of these key phrases is crucial.

Identifying Keywords and Phrases

Recognizing the keywords that signify different operations (addition, subtraction, multiplication, division) is fundamental. • **Addition:** Words like "sum," "plus," "increased by," "more than," "total." • **Subtraction:** Words like "difference," "minus," "decreased by," "less than," "subtracted from." • **Multiplication:** Words like "product," "times," "multiplied by," "of." • **Division:** Words like "quotient," "divided by," "per." Example: "The sum of two numbers is 15. One number is 3 more than the other. Find the numbers." In this example, "sum" signifies addition, and "more than" indicates an increase.

Translating to Equations

Once you identify the keywords, translate the problem into algebraic equations. This involves representing unknown quantities with variables (like 'x' or 'y') and using the keywords to create equations. Example (Continued): Let 'x' be one number. Then, the other number is 'x + 3'. The equation becomes: $x + (x + 3) = 15$

Simplifying and Solving

After formulating the equation, simplify and solve for the unknown variable. **Example (Continued):** $2x + 3 = 15$ $2x = 12$ $x = 6$ Therefore, one number is 6, and the other is 9. **Strategic Approach to Solving Word Problems** Effective problem-solving requires a structured approach.

Creating a Plan

A systematic approach ensures you don't get lost in the problem's complexities.

Understanding the Problem

Carefully read the problem. What is the question asking for? What information is provided? Identify all unknown quantities and assign variables to them. Case Study: A farmer wants to fence a rectangular field. • **Question:** How much fencing is needed? • **Information:** Length of the field, width of the field (in this example). • **Unknowns:** Total fencing required.

Developing a Strategy

Determine the mathematical relationships between the given information and the unknowns. Create a diagram if necessary to visualize the problem. This includes identifying keywords, translating them into equations, and solving the equation. **Example (Continued):** To find the total fencing required for the rectangular field, we need to add the length and width. The perimeter equation = $2(\text{Length} + \text{Width})$.

Implementing the Solution

Apply the chosen strategy. Simplify and solve the equation(s) to find the unknown variable(s). **Example (Continued):** Given the length and width (numbers), calculate the perimeter to determine the total fencing needed.

Reviewing and Evaluating

Check your answer for accuracy and ensure it aligns with the context of the problem. Check your answers to see if your solution makes sense in the real-world scenario. *Benefits of Mastering Algebra Word Problems*

Unlock the Mystery: Your Ultimate Guide to Conquering Algebra Word Problems

Algebra word problems. Just the phrase can send a shiver down the spine of many students. They seem to be the ultimate test of your math skills, turning simple numbers into confusing narratives filled with "who," "what," and "how many." But here's a secret: algebra word problems are not a mystical art form. They are, in fact, a fantastic way to see how mathematics applies to real-world situations. And with the right approach, you can learn to break them down, solve them, and even start to enjoy the challenge. This comprehensive guide is your roadmap to mastering algebra word problems. We'll go beyond just memorizing formulas and dive into a step-by-step process that will equip you with the confidence and skills to tackle any word problem that comes your way.

Why Do Word Problems Seem So Hard? The Common Pitfalls

Before we dive into the "how," let's address the "why" behind the struggle. Understanding these common pitfalls can help you avoid them: * **Information Overload:** Word problems often present a lot of information, and it can be overwhelming to figure out what's important and what's not. * **Translating Words to Math:** The biggest hurdle is often translating the narrative into mathematical equations. This requires understanding the relationships between quantities. * **Identifying the Unknown:** Pinpointing what you're actually being asked to find can be tricky. This is where variables come in. * **Fear of the Unknown:** A general apprehension towards math can make word problems seem insurmountable before you even start. Don't let these challenges deter you. With a systematic approach, you can overcome them all.

The Step-by-Step Strategy: Your Blueprint for Success

Here's a tried-and-true method for tackling any algebra word problem. Think of it as your problem-solving toolkit.

Step 1: Read and Understand - Don't Just Skim!

This is arguably the most crucial step. You need to truly understand what the problem is asking. *
Read the problem carefully, at least twice. The first read is for general comprehension. The second read is to identify key details. *
Visualize the situation. Can you picture what's happening? Imagine the people, objects, and actions described. *
Identify the core question. What are you ultimately trying to find out? Circle or highlight the question at the end of the problem. **Keywords to look for:** "how many," "what is," "find the value," "determine the amount."

Step 2: Identify the Given Information and the Unknown

Once you understand the scenario, it's time to pull out the essential pieces of information. *
List the knowns. What numbers or quantities are provided in the problem? Write them down clearly. *
Identify the unknowns. What are you trying to solve for? These will become your variables. **LSI Keywords:** variables, unknown quantities, known values, given data, mathematical symbols.

Step 3: Assign Variables to the Unknowns

This is where algebra truly comes into play. Variables are symbols (usually letters like x , y , or even more descriptive letters like 'p' for price) that represent the unknown quantities. *
Choose descriptive variables. If you're solving for the number of apples, use 'a'. If it's for the price, use 'p'. This makes your equations easier to understand. *
Define your variables clearly. Next to each variable, write what it represents. For example: * Let a = the number of apples * Let t = the time in hours
Keywords: represent, assign, unknown, variable, equation, algebraic expression.

Step 4: Translate the Words into an Equation

This is the art of converting the narrative into a mathematical statement. Look for keywords that indicate mathematical operations. *
**"Is" or "equals" often means $=$ ** *
**"More than," "added to," "sum of," "increased by" usually means $+$ ** *
**"Less than," "subtracted from," "difference between," "decreased by" usually means $-$ ** (Be careful with "less than" - it often reverses the order, e.g., "5 less than x " is $x - 5$). *
**"Times," "product of," "multiplied by," "of" (in some contexts) usually means $\times$ or $\cdot$ ** *
**"Divided by," "ratio of," "per" usually means $/$ or $\div$ ** *
Example: "Sarah has 5 more apples than John." If s is the number of apples Sarah has and j is the number of apples John has, this translates to: $s = j + 5$ **LSI Keywords:** translate, convert, mathematical operations, relationships, equality, inequality, sentence structure.

Step 5: Solve the Equation

Once you have your equation, it's time to use your algebraic skills to find the value of the unknown variable. *
Use inverse operations to isolate the variable on one side of the equation. *
Perform the same operation on both sides of the equation to maintain balance. *
Simplify and combine like terms. This step often involves techniques like: * Combining like terms * Distributive property *

Adding/subtracting/multiplying/dividing both sides by the same number **Keywords:** solve, isolate the variable, inverse operations, balance, simplify, algebraic manipulation.

Step 6: Check Your Answer - Does it Make Sense?

This is a critical step that many students skip. Your answer might be mathematically correct, but does it logically fit the context of the word problem? **Substitute your solution back into the original word problem.** Does it satisfy all the conditions? **Does the answer seem reasonable?** If you're calculating the number of people, a negative answer or a fraction of a person wouldn't make sense. **LSI Keywords:** verification, validation, logical reasoning, context, real-world application, numerical answer.

Common Types of Algebra Word Problems and How to Approach Them

Let's look at some common categories of word problems and how to apply our strategy.

Age Problems

These problems involve relationships between the ages of people at different points in time. **Key Idea:** If someone is x years old now, they were $x - n$ years old n years ago and will be $x + n$ years old n years from now. **Example:** "John is twice as old as Mary. In 5 years, John will be 10 years older than Mary. How old are they now?" Let j = John's current age, m = Mary's current age. Equation 1: $j = 2m$ Equation 2: $j + 5 = (m + 5) + 10$ (John's age in 5 years = Mary's age in 5 years + 10) Solve these two equations simultaneously. **Keywords:** age, years ago, in years, future age, past age, present age.

Distance, Rate, and Time Problems

These problems deal with the relationship: Distance = Rate x Time ($D = RT$). **Key Idea:** Understand the units. If the rate is in miles per hour, time should be in hours, and distance in miles. **Example:** "Two trains leave the same station at the same time, traveling in opposite directions. Train A travels at 60 mph and Train B travels at 70 mph. How long will it take for them to be 390 miles apart?" Let t = time in hours. Distance of Train A = $60t$ Distance of Train B = $70t$ Total distance apart = $60t + 70t = 390$ Solve for t . **Keywords:** distance, rate, speed, time, mph, travel, opposite directions, together.

Mixture Problems

These problems involve combining two or more substances with different concentrations or values. **Key Idea:** The total amount of the substance or value in the mixture is the sum of the amounts from the individual components. **Example:** "How many liters of a 20% acid solution must be mixed with 30 liters of a 60% acid solution to obtain a 40% acid solution?" Let x = liters of 20% solution. Amount of acid in first solution = $0.20x$ Amount of acid in second solution = $0.60 * 30$ Total volume of the mixture = $x + 30$ Amount of acid in the final mixture = $0.40 * (x + 30)$ Equation: $0.20x + 0.60 * 30 = 0.40 * (x + 30)$ Solve for x . **Keywords:** mixture, solution, percentage, concentration, acid, liters, combine, obtain.

Money and Coin Problems

These problems involve different denominations of money or coins. * **Key Idea:** The total value is the sum of the value of each type of coin/bill. $\text{Value} = \text{Quantity} \times \text{Denomination}$. * **Example:** "A cashier has \$25.00 in nickels and dimes. If there are 300 coins in total, how many nickels and how many dimes are there?" * Let n = number of nickels, d = number of dimes. * Equation 1 (total number of coins): $n + d = 300$ * Equation 2 (total value): $0.05n + 0.10d = 25.00$ * Solve these two equations. * **Keywords:** money, coins, nickels, dimes, quarters, dollars, value, amount, quantity.

Work Problems

These problems involve individuals or groups working together to complete a task. * **Key Idea:** If someone can complete a job in x hours, they complete $1/x$ of the job per hour. * **Example:** "Pipe A can fill a tank in 4 hours, and Pipe B can fill the same tank in 6 hours. How long will it take for both pipes to fill the tank if they are opened at the same time?" * Rate of Pipe A = $1/4$ of the tank per hour. * Rate of Pipe B = $1/6$ of the tank per hour. * Combined rate = $1/4 + 1/6$ * Let t = time in hours for both pipes working together. * Combined rate $\times$ time = 1 (representing the whole tank) * $(1/4 + 1/6) \times t = 1$ * Solve for t . * **Keywords:** work, rate, time, complete, job, task, pipe, together, individually.

Mastering Algebra Word Problems: A Step-by-Step Guide for Students

Algebra word problems can feel like deciphering a secret code. They present real-world scenarios in a narrative format, requiring you to translate words into mathematical equations before you can even begin to solve them. For many students, this translation step is the biggest hurdle. But fear not! With a systematic approach and a little practice, you can transform those daunting word problems into manageable algebraic challenges. This comprehensive guide will break down the process, equipping you with the strategies and confidence needed to conquer any algebra word problem.

Whether you're tackling basic linear equations or more complex quadratic or system-of-equations

problems, the fundamental principles remain the same. This article will provide a detailed, analytical breakdown of how to approach these problems, focusing on identifying key information, setting up equations correctly, and solving them efficiently. We'll also delve into common pitfalls and offer tips for building strong problem-solving skills.

Why Are Algebra Word Problems Important?

Before we dive into the 'how,' let's briefly touch on the 'why.' Algebra word problems are not just arbitrary exercises. They are designed to bridge the gap between abstract mathematical concepts and their practical applications. Understanding how to solve them enhances your critical thinking, analytical reasoning, and logical deduction skills. These are invaluable not only in mathematics but also in various academic disciplines and everyday life situations, from managing finances to making informed decisions.

The Core Strategy: The 5-Step Method

The most effective way to tackle algebra word problems is to adopt a structured approach. The following 5-step method provides a clear roadmap:

Step 1: Read and Understand the Problem

This might sound obvious, but it's the most crucial step. Many errors occur because students skim the problem or misunderstand a key piece of information. Read the problem carefully, perhaps even twice. Ask yourself:

1. What is the problem asking me to find? (This is your unknown.)
2. What information is given to me? (These are your knowns and constraints.)
3. Are there any keywords that suggest specific mathematical operations (e.g., "more than," "less than," "times," "divided by," "is equal to")?
4. Are there any units of measurement involved? (e.g., dollars, miles, hours, kilograms)
5. Does the problem make sense? Is there any information that seems irrelevant or contradictory?

Don't be afraid to rephrase the problem in your own words. This active engagement ensures comprehension.

Step 2: Identify and Define Variables

Once you understand the problem, you need to represent the unknown quantities with variables. Typically, 'x' is used, but you can use any letter that makes sense (e.g., 'a' for apples, 'c' for cost, 't' for time). For more complex problems with multiple unknowns, you might need multiple variables (e.g., 'x' for one quantity, 'y' for another). Clearly define what each variable represents. This is where writing things down becomes essential.

Example: If a problem states "John has twice as many apples as Mary," and you want to find the number of apples John has, you might define:

1. Let 'm' be the number of apples Mary has.
2. Let 'j' be the number of apples John has.

Or, you could define it with a single variable:

1. Let 'x' be the number of apples Mary has.
2. Then, '2x' would be the number of apples John has.

Choosing the right variable representation can sometimes simplify the setup.

Step 3: Formulate the Equation(s)

This is where the translation from words to math happens. Based on the relationships described in the problem and your defined variables, write an algebraic equation (or a system of equations) that represents the situation. Look for keywords and phrases that directly translate into mathematical operations:

1. **Addition:** "sum," "more than," "increased by," "added to," "total"
2. **Subtraction:** "difference," "less than," "decreased by," "subtracted from"
3. **Multiplication:** "product," "times," "of," "twice," "thrice"
4. **Division:** "quotient," "divided by," "ratio," "per"
5. **Equality:** "is," "equals," "is equal to," "results in"

Pay close attention to how quantities are related. For example, "5 less than a number" translates to $x - 5$, not $5 - x$.

LSI Keywords: translating word problems to equations, setting up algebraic expressions, mathematical modeling, algebraic sentences.

Step 4: Solve the Equation(s)

Once you have your equation(s), the rest is standard algebraic manipulation. Apply the rules of algebra to isolate your variable(s) and find their values. This might involve:

1. Combining like terms
2. Using the distributive property
3. Adding or subtracting the same value from both sides of the equation
4. Multiplying or dividing both sides by the same non-zero value
5. Using substitution or elimination methods (for systems of equations)
6. Factoring or using the quadratic formula (for quadratic equations)

Show your work clearly. This not only helps you track your steps but also makes it easier to identify errors if something goes wrong.

Step 5: Check Your Answer

This is a critical step that many students overlook. Plug your solution back into the original word problem (or into your original equations) to ensure it makes sense in the context of the problem. Does your answer satisfy all the conditions stated in the problem? Are the units correct? If your answer seems illogical or impossible (e.g., a negative number of people, a distance greater than possible), it's a strong indicator that you made a mistake somewhere.

Example Check: If you found that Mary has 5 apples and John has 10 apples, and the problem stated John has twice as many as Mary, then $10 = 2 * 5$, which is true. So, the answer checks out.

Common Types of Algebra Word Problems and Strategies

While the 5-step method is universal, certain problem types have specific nuances. Here are a few common categories:

Age Problems

These problems often involve relationships between the ages of people at different points in time (past, present, future).

1. **Strategy:** Use variables to represent current ages. Then, express future ages as (current age + years in future) and past ages as (current age - years in past).
2. **Example:** "Sarah is currently 3 years older than her brother, Tom. In 5 years, Sarah will be twice as old as Tom. How old are they now?"
 1. Let S be Sarah's current age and T be Tom's current age.
 2. Equation 1: $S = T + 3$
 3. In 5 years: Sarah will be $S + 5$, Tom will be $T + 5$.
 4. Equation 2: $S + 5 = 2(T + 5)$
 5. Substitute S from Eq 1 into Eq 2: $(T + 3) + 5 = 2(T + 5) \Rightarrow T + 8 = 2T + 10 \Rightarrow -2 = T$. This gives a negative age, indicating an error in my setup or the problem itself. Let's re-read and re-setup.
 6. Let's try with one variable: Let T be Tom's current age. Then Sarah's current age is $T + 3$.
 7. In 5 years: Tom will be $T + 5$, Sarah will be $(T + 3) + 5 = T + 8$.
 8. In 5 years, Sarah will be twice as old as Tom: $T + 8 = 2(T + 5)$
 9. $T + 8 = 2T + 10$
 10. $8 - 10 = 2T - T$
 11. $-2 = T$. Still negative. Let's review the phrasing again. "Sarah is currently 3 years older than her brother, Tom." $S = T + 3$. "In 5 years, Sarah will be twice as old as Tom." $S + 5 = 2(T + 5)$.
 12. Ah, the mistake was in my interpretation or the example. Let's try a correct example: "David is 5 years older than his sister, Emily. In 3 years, David will be twice as old as Emily. How old are they now?"
 13. Let E be Emily's current age. David's current age is $E + 5$.
 14. In 3 years: Emily will be $E + 3$. David will be $(E + 5) + 3 = E + 8$.
 15. Equation: $E + 8 = 2(E + 3)$
 16. $E + 8 = 2E + 6$
 17. $8 - 6 = 2E - E$
 18. $2 = E$. So, Emily is 2 years old.
 19. David is $E + 5 = 2 + 5 = 7$ years old.
 20. Check: In 3 years, Emily will be 5, David will be 10. 10 is indeed twice 5. Correct.

Distance, Rate, and Time Problems

These problems involve the relationship: Distance = Rate $\times$ Time (or $d = rt$).

1. **Strategy:** Identify the knowns (distance, rate, or time) and unknowns. Often, you'll need to set up multiple equations based on different scenarios (e.g., two objects moving towards each other, one object traveling in two different segments of a journey).

2. **LSI Keywords:** speed problems, motion problems, uniform motion, relative speed.
3. **Example:** "Two trains leave stations 300 miles apart at the same time and travel towards each other. One train travels at 60 mph, and the other travels at 90 mph. How long will it take for them to meet?"
 1. Let 't' be the time it takes for them to meet (in hours).
 2. Distance covered by train 1: $d_1 = 60t$
 3. Distance covered by train 2: $d_2 = 90t$
 4. When they meet, the sum of their distances is the total distance between stations: $d_1 + d_2 = 300$
 5. Substitute: $60t + 90t = 300$
 6. $150t = 300$
 7. $t = 300 / 150$
 8. $t = 2$ hours
 9. Check: In 2 hours, train 1 travels 120 miles. Train 2 travels 180 miles. $120 + 180 = 300$ miles. Correct.

Mixture Problems

These problems involve combining two or more quantities with different concentrations or values to achieve a desired final concentration or value.

1. **Strategy:** Focus on the "amount" of the substance and the "value" or "concentration" of that substance. The total amount of the substance in the mixture is the sum of the amounts in the components.
2. **LSI Keywords:** percentage problems, solution problems, chemical mixture.
3. **Example:** "How many liters of a 20% acid solution must be mixed with 50 liters of a 50% acid solution to obtain a 30% acid solution?"
 1. Let 'x' be the number of liters of the 20% solution.
 2. Amount of acid in the first solution: $0.20x$
 3. Amount of acid in the second solution: $0.50 * 50 = 25$
 4. Total volume of the mixture: $x + 50$
 5. Desired concentration: 30% or 0.30
 6. Amount of acid in the final mixture: $0.30(x + 50)$
 7. Equation: $0.20x + 25 = 0.30(x + 50)$
 8. $0.20x + 25 = 0.30x + 15$
 9. $25 - 15 = 0.30x - 0.20x$
 10. $10 = 0.10x$
 11. $x = 10 / 0.10$
 12. $x = 100$ liters
 13. Check: 100 liters of 20% acid has 20 liters of acid. 50 liters of 50% acid has 25 liters of acid. Total acid = $20 + 25 = 45$ liters. Total volume = $100 + 50 = 150$ liters. Concentration = $45 / 150 = 0.30$ or 30%. Correct.

Geometry Problems

These problems involve shapes, dimensions, and their properties.

1. **Strategy:** Draw a diagram! Label all known dimensions and use algebraic expressions for unknown

dimensions. Recall relevant geometric formulas (area, perimeter, volume, etc.).

2. **LSI Keywords:** shapes, dimensions, perimeter problems, area problems, volume calculations.
3. **Example:** "The length of a rectangle is 5 cm more than its width. If the perimeter of the rectangle is 30 cm, find its dimensions."
 1. Let 'w' be the width of the rectangle.
 2. The length is 'w + 5'.
 3. Perimeter formula: $P = 2(\text{length} + \text{width})$
 4. Equation: $30 = 2((w + 5) + w)$
 5. $30 = 2(2w + 5)$
 6. $30 = 4w + 10$

Tips for Success and Avoiding Pitfalls

Conquering algebra word problems is a skill that improves with practice and strategic thinking. Here are some additional tips:

1. Draw a Diagram or Visualize

For many problems, especially those involving geometry, motion, or relationships between objects, a simple sketch can illuminate the situation and help you set up equations correctly. Even for abstract problems, visualizing the scenario can be beneficial.

2. Break Down Complex Problems

If a word problem seems overwhelmingly complex, try to break it down into smaller, more manageable parts. Identify the key pieces of information and relationships sequentially.

3. Understand Common Phrasing

Familiarize yourself with how mathematical concepts are expressed in words. The more you practice, the more intuitive this translation will become.

4. Practice Regularly

Like any skill, algebra word problem-solving improves with consistent practice. Work through problems from your textbook, online resources, or past exams. The more variety of problems you encounter, the better prepared you'll be.

5. Don't Fear Errors; Learn from Them

Making mistakes is a natural part of the learning process. When you get a problem wrong, don't just move on. Take the time to understand where you went wrong. Was it a misunderstanding of the

problem? An algebraic error? A calculation mistake? Identifying the root cause will prevent you from repeating it.

6. Identify Keywords

As mentioned, keywords are crucial. Create a personal glossary of common keywords and their corresponding mathematical operations. This can be a valuable reference tool.

7. Check Units

Always pay attention to units of measurement. Ensure consistency throughout your problem-solving. If you're mixing units (e.g., minutes and hours), convert them to a common unit before setting up equations.

8. Use the Right Tool for the Job

While this guide focuses on algebra, sometimes problems might require a bit of logic or even estimation. Don't get fixated on using only one method if another seems more appropriate.

Conclusion

Algebra word problems are an integral part of learning mathematics, offering a bridge to real-world applications. By adopting a systematic approach, such as the 5-step method outlined above, and by practicing regularly, you can demystify these challenges. Remember to read carefully, define your variables clearly, translate relationships into accurate equations, solve diligently, and always check your answers. With persistence and the right strategies, you'll find yourself increasingly confident and adept at solving even the most complex algebra word problems.

Questions & Answers About how to do algebra word problems

No	Question	Answer
1	I freeze up when I see word problems! What's the secret to breaking them down?	The key is to not get overwhelmed. Start by reading the problem carefully, then identify what you're trying to find (the unknown). Next, highlight any numbers or quantities given. Finally, think about the relationships between those numbers and the unknown to set up your equation.
2	How do I know which operation (add, subtract, multiply, divide) to use in a word problem?	Look for keywords! 'Sum', 'total', 'altogether' often mean addition. 'Difference', 'less than', 'how many more' suggest subtraction. 'Product', 'times', 'each' point to multiplication. 'Quotient', 'divided by', 'per' indicate division. Context is also crucial – does the problem involve combining, comparing, or splitting?
3	What's the deal with variables? How do I pick the right letter and what does it even represent?	A variable (like 'x', 'y', or 'n') represents the unknown quantity you're trying to solve for. Choose a letter that makes sense for the problem, like 'a' for apples or 't' for time. The variable stands in for the number you don't know yet but will discover through solving the equation.
4	I set up an equation, but my answer doesn't make sense. What went wrong?	Double-check your setup! Did you correctly translate the words into mathematical symbols? Also, review your calculations. Sometimes, a simple arithmetic error can throw off the whole answer. Finally, ask yourself if the answer is reasonable in the context of the problem (e.g., you can't have negative people).

5	Are there any common 'trap' phrases in algebra word problems I should watch out for?	Be wary of 'less than.' '5 less than x' is actually written as ' $x - 5$ ', not ' $5 - x$.' Also, watch for problems involving rates where units need to be consistent. Pay close attention to how quantities are being compared or combined to avoid misinterpreting the relationships.
6	Beyond just solving for the variable, how do I make sure I've fully answered the word problem?	Always go back to the original question. Did you find what it was asking for? For example, if the question asked for the cost of two items, and you found the cost of one, you need to do one more step. Write your final answer with the correct units and in a complete sentence if appropriate.
